• If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

The ARMv8 abstraction of the cache hierarchy
These following subsections describe the ARMv8 abstraction of the cache hierarchy:
• Cache maintenance instructions that operate by VA.
• Cache maintenance instructions that operate by set/way.

Cache maintenance instructions that operate by VA
The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:
• Performed to the Point of Coherency.
• Performed to the Point of Unification.
• When ARMv8.2-DCPoP is implemented, performed to the Point of Persistence.
See Terms used in describing the cache maintenance instructions on page D4-2360 for definitions of these terms, and for more information about possible meanings of VA.

A64 Cache maintenance instructions on page D4-2364 lists the VA-based maintenance instructions.
The CTR_EL0 holds minimum line length values for:
• The instruction caches.
• The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way
A64 Cache maintenance instructions on page D4-2364 lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:
• A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
• An invalidate instruction invalidates only at the level specified.
## D4.4.8 A64 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 System instruction class in the register encoding space. For encoding details and other general information on these System instructions, see System instructions on page C3-172, SYS on page C6-1235 and Cache maintenance instructions, and data cache zero operation on page C5-343.

Table D4-3 shows the AArch64 System instructions that perform instruction or data cache maintenance. Instructions that take an argument include Xt in the entry in the System instruction column.

### Note

- In Table D4-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In general, the AArch32 instruction and data cache maintenance instructions provide equivalent functionality to the AArch64 cache maintenance instructions, see AArch32 cache and branch predictor maintenance instructions on page G4-5435. However, the data cache clean to the Point of Persistence instruction, implemented when ARMv8.2-DCPoP is implemented, is supported in AArch64 state only.

a. When HCR_EL2.{E2H,TGE} = {1, 1}, the control is from SCTLR_EL2.

b. Supported only when ARMv8.2-DCPoP is implemented.

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

---

A AArch32 instruction and data cache maintenance instructions provide equivalent functionality to the AArch64 cache maintenance instructions, see AArch32 cache and branch predictor maintenance instructions on page G4-5435. However, the data cache clean to the Point of Persistence instruction, implemented when ARMv8.2-DCPoP is implemented, is supported in AArch64 state only.
The following subsections give more information about these instructions:

- *The instruction cache maintenance instruction (IC).*
- *The data cache maintenance instruction (DC).*
- *EL0 accessibility of cache maintenance instructions* on page D4-2367.
- *General requirements for the scope of maintenance instructions* on page D4-2367.
- *Effects of instructions that operate by VA to the PoC* on page D4-2367.
- *Effects of instructions that operate by VA to the PoP* on page D4-2368.
- *Effects of instructions that operate by VA to the PoU* on page D4-2368.
- *Effects of All and set/way maintenance instructions* on page D4-2369.
- *Effects of virtualization and Security state on the cache maintenance instructions* on page D4-2369.
- *Boundary conditions for cache maintenance instructions* on page D4-2371.
- *Ordering and completion of data and instruction cache instructions* on page D4-2371.
- *Performing cache maintenance instructions* on page D4-2372.

### The instruction cache maintenance instruction (IC)

*System instructions* on page C3-172 describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H==1, the current ASID.
- The current Security state.
- Whether the instruction was executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the instruction can generate:
  - An Access flag fault.
  - A Translation fault.

- The instruction cannot generate a Permission fault, except for:
  - The possible generation of a Permission fault by the execution of an IC IVAU instruction at EL0 when the specified address does not have read access at EL0, as described in *EL0 accessibility of cache maintenance instructions* on page D4-2367.
  - The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a cache maintenance instruction that operates by VA see *VMSAv8-64 memory aborts* on page D5-2499.

See also *Ordering and completion of data and instruction cache instructions* on page D4-2371.

### The data cache maintenance instruction (DC)

*System instructions* on page C3-172 describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see *Out of range values of the Set/Way/Index fields in cache maintenance instructions* on page K1-7231 or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.
Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H is 1, the current ASID.
- The current Security state.
- Whether the instruction is executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

- The possible generation of a Permission fault by:
  - The execution of a DC IVAC instruction when the specified address does not have write permission.
  - The execution of an enabled DC * instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D4-2367.

The description of Permission faults includes possible constraints on the generation of Permission faults on cache maintenance by VA instructions.

- The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a VA to PA translation see VMSAv8-64 memory aborts on page D5-2499.

When executed at EL1, a DC ISW instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CISW instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - The value of HCR_EL2.SWIO is 1, forcing a cache clean to perform a clean and invalidate.
  - The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

When executed at EL1, a DC IVAC instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CIVAC instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

--- Note ---

The forcing of a clean instruction to perform a clean invalidate applies to the AArch32 cache maintenance instructions DCVMAC and DCISW. See AArch32 data cache maintenance instructions (DC*) on page G4-5437.

--- Note ---

When ARMv8.2-DCPoP is implemented, meaning the DC CVAP instruction is implemented, if the memory system does not support the Point of Persistence, a data cache clean to the PoP, DC CVAP, behaves as a data cache clean to the PoC, DC CVAC.

--- Note ---

- Support for the Point of Persistence does not change the definition or behavior of the CLIDR_EL1 System register.

- Because a DSB SYS instruction will not complete until all previous DC CVAP instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:

```
DMB          ; Note this can be any DMB that applies to both loads and stores
DC CVAP, Xt
DSB SYS
```

- If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the DC CVAP operation causes the Non-cacheable locations to be cleaned from those caches.

---

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.
Despite its mnemonic, DC ZVA is not a cache maintenance instruction.

See also EL0 accessibility of cache maintenance instructions and Ordering and completion of data and instruction cache instructions on page D4-2371.

**EL0 accessibility of cache maintenance instructions**

The SCTLR_EL1.UCI bit enables EL0 access for the DC CVAU, DC CVAC, DC CVAP, DC CIVAC, and IC IVAU instructions. When EL0 use of these instructions is disabled because SCTLR_EL1.UCI == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using EC = 0x18. When HCR_EL2.[E2H,TGE] == 1, the control is from SCTLR_EL2.

**Note**

DC CVAP is implemented only if ARMv8.2-DCPoP is implemented.

For these instructions read access permission is required. When the value of SCTLR_EL1.UCI is 1:

- For the DC CVAU, DC CVAC, DC CVAP, and DC CIVAC instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault might be generated.

- For the IC IVAU instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a Permission fault is generated.

For more information see the description of Permission faults. In the case of a DC * instruction executed at EL0 when the address specified cannot be read at EL0 the Permission fault is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the CTR_EL0 to discover the stride needed for cache maintenance instructions. The SCTLR_EL1.UCT bit enables EL0 access to the CTR_EL0. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using EC = 0x18.

**General requirements for the scope of maintenance instructions**

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page D4-2353, Behavior of caches at reset on page D4-2359, and Preloading caches on page B2-115.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

**Note**

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

**Effects of instructions that operate by VA to the PoC**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.
In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. Table D4-4 shows the scope of these Data and unified cache maintenance instructions.

**Table D4-4 PEs affected by cache maintenance instructions to the PoC**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA to the PoP**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. Table D4-5 shows the scope of these Data and unified cache maintenance to the PoP instructions.

**Table D4-5 PEs affected by cache maintenance instructions to the PoP**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA to the PoU**

For cache maintenance instructions that operate by VA to the PoU, Table D4-6 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table D4-6 PEs affected by cache maintenance instructions to the PoU**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable/Outer Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>
Note

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the instruction.

Effects of All and set/way maintenance instructions

The IC IALLU and DC set/way instructions apply only to the caches of the PE that performs the instruction.

The IC IALLUIS instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Note

The possible presence of system caches, as described in System level caches on page D4-2376, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.

Effects of virtualization and Security state on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D4-7 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the Specified entries are entries that the architecture requires the instruction to affect. The rules described in General behavior of the caches on page D4-2353 mean that an instruction might also affect other entries.

Table D4-7 Effects of virtualization and security on the maintenance instructions

</tbody>
</table>
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions* on page D4-2375 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, invalidate by set/way instructions can, instead, perform a clean and invalidate by set/way.

- As described in *The data cache maintenance instruction (DC)* on page D4-2365, the AArch64 Data cache invalidate instructions, DC_INVAC and DC_ISW, when executed at EL1 and EL0, and the AArch32 Data cache invalidate instructions DCIMVAC and DCISW, when executed at EL1, can be configured to perform a cache clean as well as a cache invalidation.

- TLB and instruction cache invalidate instructions executed at EL1 are broadcast across the Inner Shareable domain when all of the following is true:
  - When the value of HCR_EL2.EB is 1.
  - EL3 is not implemented, or EL3 is implemented and either SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1.

  When EL1 is using AArch64, this applies to the IC_IALU instruction. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction IC_IALUIS.

For more information about the cache maintenance instructions, see *About cache maintenance in AArch64 state* on page D4-2360, *A64 Cache maintenance instructions* on page D4-2364, and Chapter D5 *The AArch64 Virtual Memory System Architecture.*
Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, that specify an address:

- Execute in program order relative to loads or stores which:
  - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  - Use an address with the same cacheability attributes as the address passed to the data cache instruction.
- Can execute in any order relative to loads or stores which:
  - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  - Use an address with different cacheability attributes as the address passed to the data cache instruction.
  - Do not have a DMB or DSB executed between the load or store instruction and the data cache instruction.
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.
- Execute in program order relative to other data cache instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to other data cache instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

--- Note ---

Despite its mnemonic, the DC ZVA, Data Cache Zero by VA instruction is not a data cache maintenance instruction.

---

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.
Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches on page D5-2533.

Data cache zero instruction on page D4-2374 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in Completion and endpoint ordering on page B2-102.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way
instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that
operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if
this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs,
and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded
systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency
management with very large buffers or with buffers with unknown address can fail to provide the expected
coherency results because of speculation by other PEs, or possibly by other threads. The only way that these
instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that
need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that
those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large
system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems
where this will be an issue.

System level caches on page D4-2376 refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic
mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache
Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size
Identification Register, CCSIDR_EL1 on page D4-2355.

```
MRS     X0, CLIDR_EL1
AND     W3, W0, #0x0007000000     // Get 2 x Level of Coherence
LSR     W3, W3, #23
CBZ     W3, Finished
MOV     W10, #0                    // W10 = 2 x cache level
MOV     W8, #1                     // W8 = constant 0b1
Loop1: ADD     W2, W10, W10, LSR #1    // Calculate 1 x cache level
LSR     W1, W0, W2                 // extract 3-bit cache type for this level
AND     W1, W1, #0x7               // W1 = 2 x cache level
OMP     W1, #2                     // No data or unified cache at this level

ISB     // Synchronize change of CSSELR
MRS     X1, CCSIDR_EL1            // Read CCSIDR
AND     W2, W1, #7                 // W2 = log2(linelen)-4
ADD     W2, W2, #4                 // W2 = log2(linelen)
UBFX    W4, W1, #3, #10           // W4 = max way number, right aligned
CLZ     W5, W4                     // W5 = 32-log2(ways), bit position in way in DC operand
LSL     W9, W4, W5                 // W9 = max way number, aligned to position in DC operand
LSL     W16, W6, W5                // W16 = amount to decrement way number per iteration
Loop2: UBFX    W7, W1, #13, #15     // W7 = max set number, right aligned
LSL     W7, W7, W2                 // W7 = max set number, aligned to position in DC operand
LSL     W17, W8, W2                // W17 = amount to decrement set number per iteration
Loop3: ORR     W11, W10, W9        // W11 = combine way number and cache number ...
ORR     W11, W11, W7              // ... and set number for DC operand
DC      CSW, X11                   // Do data cache clean by set and way
SUBS    W7, W7, W17                // Decrement set number
B.GE    Loop3
SUBS    X9, X9, X16               // Decrement way number
B.GE    Loop2
Skip:    ADD     W10, W10, #2       // Increment 2 x cache level
CMP     W3, W10                    // Ensure completion of previous cache maintenance instruction
DSB     // Ensure completion of previous cache maintenance instruction
B.GT    Loop1
Finished:
```

Similar approaches can be used for all cache maintenance instructions.
D4.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, `DC ZVA`, writes `0x00` to each byte of a block of `N` bytes, aligned in memory to `N` bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the `DC ZVA` instruction. There are no alignment restrictions on this address.

  **Note**

  This means that each byte of the block of memory that includes the supplied address is set to zero.

- The `DCZID_EL0` register indicates the block size, `N` bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See *Configurable instruction enables and disables, and trap controls* on page D1-2208 and the description of the `DC ZVA` instruction.

The `DC ZVA` instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See *ISS encoding for an exception from a Data Abort* on page D12-2792 for more information about the encoding of the associated `ESR_ELx.ISS` field.
- If the memory region being zeroed is any type of Device memory, then `DC ZVA` generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

  **Note**

  The architecture makes no statements about whether or not a `DC ZVA` instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

Despite its mnemonic, the `DC ZVA` instruction is not a data cache maintenance instruction.

D4.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is implementation defined. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is implementation defined:
  - Cache clean by set/way, DC CSW.
  - Cache invalidate by set/way, DC ISW.
  - Cache clean and invalidate by set/way, DC CISW.
  - Instruction cache invalidate all, IC IALLU and IC IALLUS.

However, one of the following approaches must be adopted in all these cases:
1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is implementation defined whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an implementation defined Data Abort exception is generated, using the DFSC value defined for this purpose, see ISS encoding for an exception from a Data Abort on page D12-2792.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is implementation defined:
- Cache clean by virtual address, DC CVAC, DC CVAP, and DC CVAU.
- Cache invalidate by virtual address, DC IVAC.
- Cache clean and invalidate by virtual address, DC CIVAC.

However, one of the following approaches must be adopted in all these cases:
1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is implementation defined whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an implementation defined Data Abort exception is generated, using the DFSC value defined for this purpose. See ESR_ELx on page K13-7398.

In an implementation that includes EL2 enabled in the current Security state, if HCR_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry is routed to EL2.

Note

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:
- Document the implementation defined instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such implementation defined instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.
Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D11-2671.

D4.4.11 System level caches

The ARM Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR_EL1 and CLIDR_EL1, and for which the set/way cache maintenance instructions do not apply. Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

D4.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.
The ARM architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page D1-2147.

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported.

VMSAv8-64 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

A synchronous External abort on an instruction fetch, including a translation table walk on an instruction fetch, is taken precisely using the Instruction Abort exception.

A synchronous External abort on a data read or write, including a translation table walk on a data read or write, is taken precisely using the Data Abort exception.

See Synchronous exception types, routing and priorities on page D1-2190.

When ARMv8.4-DFE is implemented, all External abort exceptions on instruction fetches must be synchronous.

An asynchronous External abort is taken using the SError interrupt exception. See Asynchronous exception types, routing, masking and priorities on page D1-2198.

The effect of a failed memory access is described in Effect of Data Aborts on page D1-2195.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running, ARM recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:

- Provision for the classification of External aborts.
- Parity or ECC error reporting, RAS Extension not implemented on page D4-2378.

D4.5.1 Provision for the classification of External aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, ESR_ELx.EA, ISS[9], returns a value of 0.

If the RAS Extension is implemented:

- The ESR_ELx.SET field provides information about the state of the PE following a synchronous External abort.
- The ESR_ELx.AET field might contain more information following an asynchronous abort taken as an SError interrupt.
- The implementation might define error record registers.

For more information, see:

- ISS encoding for an exception from an Instruction Abort on page D12-2790.
• ISS encoding for an exception from a Data Abort on page D12-2792.
• ISS encoding for an SError interrupt on page D12-2836.
• ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

D4.5.2 Parity or ECC error reporting, RAS Extension not implemented

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-2172. However, when parity or ECC error reporting is implemented, it is implementation defined whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
D4.6 Memory barrier instructions

Memory barriers on page B2-103 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D4.6.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 enabled in the current Security state and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can modify the required shareability of an instruction that is executed at EL0 or EL1. Table D4-8 shows the encoding of this field.

Table D4-8 EL2 control of shareability of barrier instructions executed at EL0 or EL1

<table>
<thead>
<tr>
<th>HCR_EL2.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1, Table D4-9 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

Table D4-9 Effect of HCR_EL2.BSU on barrier instructions executed at EL1 or EL0

D4.7 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access on page D4-2381.
- Unaligned memory access on page D4-2381.
- Exclusives monitors operations on page D4-2381.
- Access permission checking on page D4-2382.
- Abort exceptions on page D4-2382.
- Memory barriers on page D4-2382.

D4.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, MemHint_RA, and MemHint_RWA constants.
- Access permissions, defined by the Permissions type.

These types are defined in Chapter J1 ARMv8 Pseudocode.

D4.7.2 Basic memory access

The two forms of the _Mem[] accessor, non-assignment (memory read) _Mem[] and assignment (memory write) _Mem[]
are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from
the underlying physical memory array of bytes.

The functions address the array using desc.paddress, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in desc.memattrs are used by the memory system to determine caching and ordering behaviors as
described in Memory types and attributes on page B2-122, Ordering and observability on page B2-98, and
Atomicity in the Arm architecture on page B2-92.

An additional parameter to the _Mem[] accessor defines the access type, for example normal, exclusive, ordered, or
streaming, and whether the access is made as part of a translation table walk.

The actual implemented array of physical memory might be smaller than the maximum size permitted by the
architecture. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space
might give rise to External aborts or a System Error.

--- Note ---

The permitted physical memory size is:

- $2^{52}$ bytes in an implementation that includes ARMv8.2-LPA. However, only $2^{48}$ bytes are accessible using
  the 4KB or 16KB translation granule.
- $2^{48}$ bytes otherwise.
PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

**D4.7.3 Aligned memory access**

The two MemSingle[] accessors, non-assignment (memory read) AArch64.MemSingle[] and assignment (memory write) AArch64.MemSingle[], make atomic, little-endian accesses of size bytes. These functions are defined in Chapter J1 ARMv8 Pseudocode.

**D4.7.4 Unaligned memory access**

The two Mem[] accessors, Non-assignment (memory read) Mem[] and Assignment (memory write) Mem[], make accesses of the required type. If an access is not architecturally defined to be atomic, Mem[] synthesizes accesses from multiple calls to AArch64.MemSingle[]. It also reverses the byte order if the access is big-endian.

The AArch64.CheckAlignment() function checks the alignment of memory accesses.

**D4.7.5 Exclusives monitors operations**

The AArch64.SetExclusiveMonitors() function sets the Exclusives monitors for a block of bytes, the size of which is determined by size, at the virtual address defined by address.

The AArch64.ExclusiveMonitorsPass() function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch64.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by AArch64.ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONstrained UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result isanded with the result of IsExclusiveGlobal() with the same parameters.

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is
IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

These functions are defined in Chapter J1 ARMv8 Pseudocode.

**D4.7.6 Access permission checking**

The function AArch64.CheckPermission() is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to AArch64.NoFault().

These functions are defined in Chapter J1 ARMv8 Pseudocode.

The interpretation of access permission is shown in Memory access control on page D5-2456.

**D4.7.7 Abort exceptions**

The function AArch64.Abort() generates either a Data Abort or an Instruction Abort exception by calling AArch64.DataAbort() or AArch64.InstructionAbort(). It also can generate a debug exception for debug related faults, see Chapter D2 AArch64 Self-hosted Debug.

The function AArch64.DataAbort() generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See ISS encoding for an exception from a Data Abort on page D12-2792. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, AArch64.DataAbort() also sets the FAR to the VA of the abort.

The function AArch64.InstructionAbort() generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx, see ISS encoding for an exception from an Instruction Abort on page D12-2790. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, AArch64.InstructionAbort() also sets the FAR to the VA of the abort.

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode description of the MMU faults on page D5-2508 provides a number of wrappers to generate FaultRecords.

The function AArch64.NoFault() returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

**D4.7.8 Memory barriers**

The definition for the memory barrier functions is given by the enumerations MBReqDomain and MBReqTypes.

These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures DataMemoryBarrier, DataSynchronizationBarrier, and InstructionSynchronizationBarrier perform the memory barriers.*
Chapter D5
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSA) on page D5-2384, the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- About the Virtual Memory System Architecture (VMSA) on page D5-2384.
- The VMSA v8-64 address translation system on page D5-2392.
- VMSA v8-64 translation table format descriptors on page D5-2444.
- Memory access control on page D5-2456.
- Memory region attributes on page D5-2476.
- Virtualization Host Extensions on page D5-2486.
- VMSA v8-64 memory aborts on page D5-2499.
- Nested virtualization on page D5-2492.
- Translation Lookaside Buffers (TLBs) on page D5-2509.
- TLB maintenance requirements and the TLB maintenance instructions on page D5-2515.
- Caches in a VMSA v8-64 implementation on page D5-2533.
D5.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the ARMv8 Virtual Memory System Architecture (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSA-64, as defined in ARMv8 VMSA naming. See The ARMv8 VMSA when some Exception levels are using AArch32 for information about the VMSA in other contexts.

A VMSA provides a Memory Management Unit (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the virtual addresses (VAs) used by the PE onto the physical addresses (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in The VMSA-64 address translation system on page D5-2392.

VMSA-64 supports tagging of VAs, as described in Address tagging in AArch64 state on page D5-2386. As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSA-64 for an implementation that includes all of the Exception levels. The implemented Exception levels and the resulting translation stages and regimes on page D5-2396 describes the differences in the VMSA if some Exception levels are not implemented.

The following sections give more information about the VMSA:

- ARMv8 VMSA naming.
- The ARMv8 VMSA when some Exception levels are using AArch32.
- VMSA address types and address spaces on page D5-2385.
- Address tagging in AArch64 state on page D5-2386.
- Pointer authentication in AArch64 state on page D5-2388.

D5.1.1 ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

- **VMSA**: The overall translation scheme, within which an address translation has one or two stages.
- **VMSA-32**: The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32. VMSA-32 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch32.
- **VMSA-64**: The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64. VMSA-64 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch64.

D5.1.2 The ARMv8 VMSA when some Exception levels are using AArch32

As stated at the start of the chapter, this chapter describes VMSA-64, the ARMv8 VMSA that applies to an Exception level that is using AArch64. However, when a higher Exception level is using AArch64, and therefore using VMSA-64, lower Exception levels can be using AArch32. Chapter G5 The AArch32 Virtual Memory System Architecture describes VMSA-32, meaning it describes:

- The translation stages and translation regimes when EL3 is using AArch32.
- Any stages of address translation that are using VMSA-32 when EL3 is using AArch64.

However, a PE can be executing at EL0 using AArch32 when the next higher Exception level is using AArch64, for example when EL0 is using AArch32 and EL1 is using AArch64. When this is the case execution at EL0 uses a VMSA-64 translation regime as described in Constraints on accesses from EL0 when EL0 is using AArch32 on page D5-2395.
D5.1.3 VMSA address types and address spaces

A description of the VMSA refers to the following address types.

--- Note ---
These descriptions relate to the VMSA v8 description and therefore give more detail than the generic definitions given in the glossary.

---

**Virtual address (VA)**

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

--- Note ---
This means that an address held in the PC, LR, SP, or an ELR, is a VA.

---

In AArch64 state, the VA has a maximum address width of either 48 bits or, when ARMv8.2-LVA is implemented and the 64KB translation granule is used, 52 bits. As *About address translation and supported input address ranges* on page D5-2395 describes, a stage of address translation can support one or two VA ranges:

**Translation stage can support only a single VA range**

For a translation stage that supports a single VA range, a 48-bit VA width gives a VA range of $0x0000000000000000$ to $0x0000FFFFFFFFFFFF$. If ARMv8.2-LVA is implemented and the 64KB translation granule is used, for a translation regime that supports a single VA range, the 52-bit VA width gives a VA range of $0x0000000000000000$ to $0x000FFFFFFFFFFFF$.

**Translation stage can support two VA ranges**

For a translation stage that supports two VA subranges, one at the bottom of the full 64-bit address range, and one at the top, as follows:

- The bottom VA range runs up from address $0x0000000000000000$.
  With a maximum VA width of 48 bits this gives a VA range of $0x0000000000000000$ to $0x0000FFFFFFFFFFFF$.
  With a maximum VA width of 52 bits this gives a VA range of $0x0000000000000000$ to $0x000FFFFFFFFFFFF$.
- The top VA subrange runs up to address $0xFFFFFFFFFFFFFFFF$.
  With a maximum VA width of 48 bits this gives a VA range of $0xFFFFFFFF00000000$ to $0xFFFFFFFFFFFFFFFF$.
  With a maximum VA width of 52 bits this gives a VA range of $0xFFFFFFFF00000000$ to $0xFFFFFFFFFFFFFFFF$.

Reducing the VA width for this subrange increases the bottom address of the range.

--- Note ---
- When ARMv8.1-VHE is not implemented, the only translation stage that can support two VA ranges is stage 1 of the EL1&0 translation regime.
- When ARMv8.1-VHE is implemented and the value of HCR_EL2 is 1, stage 1 of the EL2, or EL2&0, translation regime also can support two VA ranges.

A 48-bit VA range corresponds to an address space of 256TB. A 52-bit VA range corresponds to an address space of 4PB.

Each translation regime that takes a VA as an input address can be configured to support fewer than the maximum number of bits of VA space, see *Address size configuration* on page D5-2399.

**Intermediate physical address (IPA)**

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
• The IA for the stage 2 translation.
In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

The EL3, Secure EL1, and if ARMv8.4-SecEL2 is implemented, Secure EL2 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:
• A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
• When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see Address size configuration on page D5-2399.

Physical address (PA)
The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3, Secure EL1, and if ARMv8.4-SecEL2 is implemented, Secure EL2 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:
• A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
• When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see Address size configuration on page D5-2399.

D5.1.4 Address tagging in AArch64 state
In AArch64 state, the ARMv8 architecture supports the tagging of addresses. In these cases the top eight bits of the VA are ignored when determining:
• If the translation system is enabled, whether the address is out of range and therefore causes a Translation fault.
• If the translation system is not enabled, whether the address is out of range and therefore causes an Address size fault.
• Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses when stage 1 translation can support two VA ranges
The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

<table>
<thead>
<tr>
<th>VA[55]</th>
<th>TCR_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>==0</td>
<td></td>
</tr>
<tr>
<td>==1</td>
<td>TCR_ELx.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_ELx holds the base address of the translation tables used to translate the address.</td>
</tr>
</tbody>
</table>

For addresses when stage 1 translation supports only a single VA range
TCR_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address.
The TCR_ELx.TBI\{n\} bit determines whether address tags are used regardless of whether the corresponding translation regime is enabled.

When ARMv8.3-PAuth is implemented, TBID\{n\} bits are added to TCR_ELx registers.

When a TCR_ELx.TBI\{n\} bit enables the use of address tagging, the corresponding TBID\{n\} bit determines whether address tagging is used for both instruction and data addresses, or only for data addresses.

The bits added are:

- TCR_EL1.{TBID1, TBID0}.
- If stage 1 of the EL2 or EL2&0 translation regime supports two VA ranges, TCR_EL2.{TBID1, TBID0}. Otherwise, TCR_EL2.TBID.
- TCR_EL3.TBID.

Restricting address tagging to data addresses means instruction addresses can use larger Pointer authentication code fields. See Pointer authentication in AArch64 state on page D5-2388.

An address tag enable bit also has an effect on the PC value in the following cases:

- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- Any branch within the controlled Exception level, unless that branch generates an Illegal exception return.
- On performing an exception return that is not an Illegal exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.

On an Illegal exception return, bits[63:32] of the PC become UNKNOWN.

- Exiting from debug state to the controlled Exception level.

As an example of what is meant by the controlled Exception level, TCR_EL3.TBI controls this effect for:

- A branch or procedure return within EL3.
- Taking an exception to EL3.
- Performing an exception return or a debug state exit to EL3.

The effect of the controlling TBI\{n\} bit is:

**For a translation regime where stage 1 translation can support two VA ranges**

If the controlling TBI\{n\} bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign-extension of bit[55] of that address.

**For a translation regime where stage 1 translation supports only a single VA range**

If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

However, when ARMv8.3-PAuth is implemented and the value of a TCR_ELx.TBID\{n\} field is 1, the Effective value of the corresponding TCR_ELx.TBI\{n\} field is 0 for any of:

- A branch or procedure return within an Exception level.
- Taking an exception to an Exception level.
• Exception return to an Exception level.
• Exit from Debug state to an Exception level.

The `AddrTop()` pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the VA is using tagging. For a translation regime where the stage 1 translation supports two VA ranges, this pseudocode includes the selection between `TTBR0_ELx` and `TTBR1_ELx` described in Selection between `TTBR0_ELx` and `TTBR1_ELx when two VA ranges are supported` on page D5-2429.

Note

The required behavior prevents a tagged address being propagated to the program counter.

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the VA returned in the FAR.

D5.1.5 Pointer authentication in AArch64 state

ARMv8.3-PAuth adds functionality that supports the authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load. This functionality is supported only in AArch64 state.

For pointer authentication, the new functionality provides:

• An instruction that inserts a Pointer Authentication Code (PAC) into the upper bits of a register. The bits used are the extension bits that do not hold valid address bits. The inserted PAC value is calculated from the value of the register and one other 64-bit value.

• An instruction that extracts the PAC from the upper bits of a register, and checks that the value is correct, based on the value of the register and one other 64-bit value, and:
  — If the value is correct, replaces the PAC with the extension bits.
  — Otherwise, replaces the PAC with the extension bits, except that two bits of the extension are set to a fixed unique number. This means that, if the register is used as the target of an indirect branch, execution branches to an address that generates a Translation fault because the VA is not mapped.

• An instruction that removes the PAC, replacing it with the extension bits, without any verification.

Multiple versions of these instructions are provided to support different use cases. These include instructions that combine a pointer authentication operation with another operation. Pointer authentication instructions on page C3-174 summarizes these instructions.

In addition, ARMv8.3-PAuth provides a generic authentication instruction, `PACGA`, that generates a 32-bit PAC from two 64-bit values.

Note

The `PACGA` instruction can be used to provide protection for small blocks of memory. Instructions can be chained to allow protection of an arbitrary-sized block.

For the Pointer authentication instructions, it is IMPLEMENTATION DEFINED whether PACs are generated using:

• The QARMA algorithm, see The QARMA Block Cipher Family. When this is the case, the value of `ID_AA64ISAR1_EL1.APA` is 0b0001.

• An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of `ID_AA64ISAR1_EL1.API` is 0b0001.

Similarly, for the `PACGA` instruction, it is IMPLEMENTATION DEFINED whether PACs are generated using:

• The QARMA algorithm, see The QARMA Block Cipher Family. When this is the case, the value of `ID_AA64ISAR1_EL1.GPA` is 0b0001.

• An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of `ID_AA64ISAR1_EL1.GPI` is 0b0001.
The pseudocode descriptions of the operation of these instructions describe the use of the QARMA algorithm. When an IMPLEMENTATION DEFINED algorithm is used the `ComputePAC()` function:

- Must have the same arguments as the function defined in this Manual.
- For a set of arguments passed to the function, must give the same result for all PEs that a thread of execution could migrate between.

**ARMv8.3-PAuth** is implemented if the value of at least one of `ID_AA64ISAR1_EL1.{APA, API, GPA, GPI}` is `0b0001`.

--- **Note** ---

Pointer authentication functionality is useful only when address translation is enabled. However, this functionality is the same whether address translation is enabled or disabled.

---

The following sections give more information about the **ARMv8.3-PAuth** functionality:

- Supported PAC field and relation to the use of address tagging.
- Keys for PAC generation and verification on page D5-2390.
- System register control of pointer authentication on page D5-2390.

**Supported PAC field and relation to the use of address tagging**

As stated earlier in this section, the PAC is held in the extension bits of a register, that do not hold valid address bits. However, as described in *Address tagging in AArch64 state* on page D5-2386, when address tagging is used the tag is held in `Xn[63:56]`. Therefore, when `Xn` is a 64-bit register holding an address:

**When address tagging is used**

The PAC field is `Xn[54:bottom_PAC_bit]`.

**When address tagging is not used**

The PAC field is `Xn[63:56, 54:bottom_PAC_bit]`.

In the PAC field definitions, `bottom_PAC_bit == 64 - TCR_ELx.TnSZ`.

--- **Note** ---

`Xn[55]` determines whether the address lies in the upper or lower address range for the purpose of determining whether address tagging is used, see *Address tagging in AArch64 state* on page D5-2386. The value of `Xn[55]` is the value of `n` in `TnSZ`. Therefore, it also determines whether `Xn[63:56]` are part of the PAC field, and which of `TCR_ELx.{T0SZ, T1SZ}` determines the value of `bottom_PAC_bit`.

---

If the value of `TCR_ELx.TnSZ` is outside its permitted range then it is **CONSTRAINED UNPREDICTABLE** whether the value used to determine `bottom_PAC_bit` is the programmed value of the field, or is forced to the maximum or minimum permitted value of the field. However, if the PE treats an out of range `TnSZ` value as the maximum or minimum permitted value of the field for all purposes except reading the value of the field then that behavior also applies to determining `bottom_PAC_bit`.

**ARMv8.3-PAuth** adds a new control to `TCR_ELx`, that disables the use of address tagging for instruction addresses, see *Address tagging in AArch64 state* on page D5-2386.

--- **Note** ---

This control means software can use larger PAC field for instruction addresses, while using tagging and the smaller PAC field for data addresses.
Keys for PAC generation and verification

For pointer authentication, two 128-bit keys are provided for each of instruction addresses and data addresses, and a fifth 128-bit key is provided for the generic authentication instruction, as follows:

Keys for instruction address PACs

APIAKey_EL1
The concatenation of the register values APIAKeyHi_EL1:APIAKeyLo_EL1.

APIBKey_EL1
The concatenation of the register values APIBKeyHi_EL1:APIBKeyLo_EL1.

Keys for data address PACs

APDAKey_EL1
The concatenation of the register values APDAKeyHi_EL1:APDAKeyLo_EL1.

APDBKey_EL1
The concatenation of the register values APDBKeyHi_EL1:APDBKeyLo_EL1.

Key for generic authentication

APGAKey_EL1
The concatenation of the register values APGAKeyHi_EL1:APGAKeyLo_EL1.

Note
Keys are not banked by Exception level. ARM expects software to switch the keys between Exception levels, typically by swapping the values with zero so that the current key values are not present in memory.

System register control of pointer authentication

ARMv8.3-PAuth adds controls to the SCTLR_ELx registers that enable generation and validation of PACs for data and instruction addresses. Formally, the definition of these fields is that when the functionality is disabled the AddPAC<I|D><A|B>() and Auth<I|D><A|B>() pseudocode functions return the value of the first parameter passed to them. This means:

- Except for PACGA, the instructions listed in Table C3-11 on page C3-174, that add a PAC to an address in a register, execute as NOPs.
- The instructions listed in Table C3-12 on page C3-175, that authenticate a pointer, execute as NOPs.
- For the Combined instructions listed in Table C3-14 on page C3-176, the Auth<I|D><A|B>() function has no effect on the operation of the instruction, which operates as the equivalent non-Authenticate pointer instruction. This means that, for example:
  - A RETAA instruction operates as a RET instruction.
  - A LDRAAA Xt, [Xn, #<simm10>!] instruction operates as a LDR Xt, [Xn, #<simm10>:000]! instruction.

These controls do not affect the PACGA and XPAC* instructions, that are always enabled.

The controls added to the SCTLR_ELx registers are:

- **EnIA**: Controls instructions that apply to PACs for instruction addresses that are generated using the APIAKey_EL1 key.
- **EnIB**: Controls instructions that apply to PACs for instruction addresses that are generated using the APIBKey_EL1 key.
- **EnDA**: Controls instructions that apply to PACs for data addresses that are generated using the APDAKey_EL1 key.
- **EnDB**: Controls instructions that apply to PACs for data addresses that are generated using the APDBKey_EL1 key.

See the SCTLR_ELx. {EnIA, EnIB, EnDA, EnDB} field descriptions for more information.
Note

These fields are RES0 in versions of the architecture before ARMv8.3, and therefore should be written as 0 by legacy software.
D5.2 The VMSAv8-64 address translation system

The following subsections describe the VMSAv8-64 address translation system, that maps VAs to PAs:

- About the VMSAv8-64 address translation system.
- The implemented Exception levels and the resulting translation stages and regimes on page D5-2396.
- Controlling address translation stages on page D5-2397.
- Memory translation granule size on page D5-2406.
- Translation tables and the translation process on page D5-2412.
- Overview of the VMSAv8-64 address translation stages on page D5-2415.
- The VMSAv8-64 translation table format on page D5-2426.
- The algorithm for finding the translation table descriptors on page D5-2433.
- The effects of disabling a stage of address translation on page D5-2437.
- The implemented Exception levels and the resulting translation stages and regimes on page D5-2396.
- Pseudocode description of VMSAv8-64 address translation on page D5-2439.
- Address translation instructions on page D5-2440.

Related to this:

- VMSAv8-64 translation table format descriptors on page D5-2444 describes the translation table entries.
- Memory region attributes on page D5-2476 describes the attributes that are held in the translation table entries, including how different attributes can interact.
- Translation Lookaside Buffers (TLBs) on page D5-2509 describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.
- AArch64 Address translation examples on page K7-7284 gives detailed descriptions of typical examples of translating a VA to a final PA, and obtaining the memory attributes of that PA.

D5.2.1 About the VMSAv8-64 address translation system

The Memory Management Unit (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an input address (IA), and either:

- Returns an associated output address (OA), and the memory attributes for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. System registers are used to report any MMU faults that occur.

The process of mapping an IA to an OA is an address translation, or more precisely a single stage of address translation.

When using a VMSA, a translation regime maps a VA to a PA using one or two stages of translation, and:

- The AArch64 translation regimes on page D5-2393 defines the translation regimes.
- VMSA address types and address spaces on page D5-2385 give more information about VAs and PAs.

The translation granule specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The page size for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. The effects of disabling a stage of address translation on page D5-2437 defines how the MMU handles an access for which a required address translation stage is disabled.
This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. In addition:

- The ARMv8 VMSA when some Exception levels are using AArch32 on page D5-2384 gives information about the VMSA when some Exception levels are using AArch32.
- The implemented Exception levels and the resulting translation stages and regimes on page D5-2396 describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called translation tables. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different levels of lookup.

Translation table entries can be cached in a Translation Lookaside Buffer (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:
- For accesses made from Secure state, whether the access is to the Secure or Non-secure address map.
- Memory access permissions.
- Memory region attributes.

For more information, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449.

The following subsections give more information:
- The AArch64 translation regimes.
- About address translation and supported input address ranges on page D5-2395.
- The VMSAv8-64 translation table format on page D5-2396.

The AArch64 translation regimes

The architecture defines a number of translation regimes, where a translation regime comprises either:
- A single stage of address translation.
  - This maps an input VA to an output PA.
- Two, sequential, stages of address translation, where:
  - Stage 1 maps an input VA to an output IPA.
  - Stage 2 maps an input IPA to an output PA.

Figure D5-1 shows these translation stages and translation regimes when EL3 is using AArch64.

Translation regimes, when EL3 is using AArch64

| EL1&0, when EL2 is disabled | VA | EL1&0 stage 1 | Controlled from EL1† | PA |
| EL1&0, when EL2 is enabled | VA | EL1&0 stage 1 | Controlled from EL1† | IPA | EL1&0 stage 2 | Controlled from EL2† | PA |
| EL2 or EL2&0‡ | VA | EL2, or EL2&0‡, stage 1 | Controlled from EL2† | PA |
| EL3 | VA | EL3 stage 1 | Controlled from EL3 | PA |

† Typically controlled from this Exception level, but also accessible from higher Exception levels
‡Only when the implementation includes ARMv8.1-VHE and the value of HCR_EL2.E2H is 1

Figure D5-1 VMSAv8 AArch64 translation regimes, translation stages, and associated controls
This means that in VMSAv8-64 the set of translation regimes is:

**The Secure EL1&0 translation regime, when EL2 is disabled**

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is \{0,0\}.

**The Non-secure EL1&0 translation regime, when EL2 is disabled**

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is \{0,0\}.

  The memory access will be Non-secure when SCR_EL3.NS is 1.

**The Secure EL1&0 translation regime, when EL2 is enabled**

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current virtual machine. This regime has two stages of lookup:

  **Stage 1** Maps VAs to IPAs. This stage can support two VA ranges and the use of ASIDs.

  **Stage 2** Maps IPAs to PAs. This stage supports a single IPA range.

This translation regime is used:

- For memory access from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is \{0, 0\}.

**The Non-secure EL1&0 translation regime, when EL2 is enabled**

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current virtual machine. This regime has two stages of lookup:

  **Stage 1** Maps VAs to IPAs. This stage can support two VA ranges and the use of ASIDs.

  **Stage 2** Maps IPAs to PAs. This stage supports a single IPA range.

This translation regime is used:

- For memory access from EL1 or EL0 when the value of HCR_EL2.{E2H, TGE} is \{0, 0\}.

**The Secure EL2&0 translation regime**

When ARMv8.1-VHE is implemented, this regime has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL0 when the value of HCR_EL2.{E2H, TGE} is \{1,1\}.
- For memory accesses from EL2 when the value of HCR_EL2.E2H is 1.

This translation regime is present when ARMv8.4-SecEL2 is implemented and enabled.

**The Non-secure EL2&0 translation regime**

When ARMv8.1-VHE is implemented, this regime has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

This translation regime is used:

- For memory accesses from EL0 when the value of HCR_EL2.{E2H, TGE} is \{1, 1\}.
- For memory accesses from EL2 when the value of HCR_EL2.E2H is 1.

**The Secure EL2 translation regime**

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

This translation regime is used:

- For all memory accesses from EL2 in implementations that do not include ARMv8.1-VHE.
• For all memory access from EL2, when ARMv8.1-VHE is implemented and HCR_EL2.E2H is 0.

This translation regime is present when ARMv8.4-SecEL2 is implemented and enabled.

The Non-secure EL2 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

This translation regime is used:
• For all memory accesses from EL2 in implementations that do not include ARMv8.1-VHE.
• For all memory access from EL2, when ARMv8.1-VHE is implemented and HCR_EL2.E2H is 0.

The Secure EL3 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

An MMU fault might be generated by a particular stage of translation. An MMU fault is described as either a stage 1 MMU fault or a stage 2 MMU fault.

--- Note ---
• In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between IPA and PA.
• A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
  — Returns an OA that equals the IA. This is called a flat mapping of the IA to the OA.
  — Does not change the memory attributes returned by the stage 1 address translation.

---

Constraints on accesses from EL0 when EL0 is using AArch32

ARMv8 permits execution with EL0 using AArch32 when the next higher Exception level is using AArch64. This happens in the following situations:
• EL1 is using AArch64. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
• EL2 is using AArch64 and the Effective value of HCR_EL2.[E2H, TGE] is {0, 1} or {1, 0}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
• In an implementation that includes ARMv8.1-VHE, EL2 is using AArch64 and the value of HCR_EL2.[E2H, TGE] is {1, 1}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL2&0 translation regime.

In this case, accesses from EL0 using AArch32 are using:
• The stated VMSAv8-64 translation regime, EL1&0 or EL2&0.
• The AArch32 memory model.

In particular, this means the accesses from EL0 are limited to a 32-bit VA range.

About address translation and supported input address ranges

For a single stage of address translation, a Translation table base register (TTBR_ELx) indicates the start of the first translation table required for a mapping from input address (IA) to output address (OA). For a stage of address translation that supports two VA ranges each VA range is an independent mapping from IA to OA. This means that each implemented translation stage shown in VMSAv8 AArch64 translation regimes, translation stages, and associated controls on page D5-2393 requires:
• Two associated sets of translation tables if it supports two IA ranges.
• One associated set of translation tables if it supports a single IA range.
Note

- Stage 2 translations never support two IA ranges. This means that, for the translation stages that support two IA ranges the IA is always a VA.
- Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls on page D5-2430 shows how two supported VA ranges might be used.

Controlling address translation stages on page D5-2397 summarizes the System registers that control address translation by the MMU, and Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2429 gives more information about the address translation stages that support two VA ranges.

A full translation table lookup is called a translation table walk. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a level of address lookup. The final level of the lookup defines:
- The high bits of the required output address.
- The attributes and access permissions of the addressed memory.

Translation table entries can be cached in a Translation Lookaside Buffer, see Translation Lookaside Buffers (TLBs) on page D5-2509.

The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

Note

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. Chapter G5 The AArch32 Virtual Memory System Architecture describes both of these formats.

The VMSAv8-64 translation table format provides:
- Up to four levels of address lookup.
- A translation granule size of 4KB, 16KB, or 64KB.
- Input addresses of:
  - Up to 52 bits if ARMv8.2-LVA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.
- Output addresses of:
  - Up to 52 bits if ARMv8.2-LPA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.

For more information about input address and output address sizes see Address size configuration on page D5-2399.

D5.2.2 The implemented Exception levels and the resulting translation stages and regimes

About the VMSAv8-64 address translation system on page D5-2392 describes an implementation that includes all Exception levels. Controlling address translation stages on page D5-2397 describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:
- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.
Figure D5-1 on page D5-2393 shows the set of translation regimes for an implementation that implements all of the Exception levels. Table D5-1 shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the execution state being used by the highest implemented Exception level.

Table D5-1 The relation between the implemented translation stages and Exception levels for AArch64

<table>
<thead>
<tr>
<th>Translation stage</th>
<th>Requires</th>
</tr>
</thead>
<tbody>
<tr>

<td>EL3 implemented and using AArch64.</td>
</tr>
<tr>
<td>Secure EL2a stage 1</td>
<td>EL2 implemented and using AArch64.</td>
</tr>
<tr>
<td>Secure EL2&amp;0b stage 1</td>
<td>EL2 implemented and using AArch64.</td>
</tr>
<tr>
<td>Secure EL1&amp;0 stage 2</td>
<td>EL2 implemented and using AArch64.</td>
</tr>
</tbody>
</table>
| Secure EL1&0 stage 1| Either:  
  - EL3 implemented and using AArch64.  
  - Only EL1 and EL0 implemented, all operation is in Secure state, and EL1 is using AArch64. |
| Non-secure EL2 stage 1| EL2 implemented. |
| Non-secure EL2&0b stage 1| EL2 implemented. |
| Non-secure EL1&0 stage 2| EL2 implemented. |
| Non-secure EL1&0 stage 1| Any implementation except:  
  - Only EL1 and EL0 implemented, with all operation in the Secure state. |

a. This translation regime is supported only if an implementation includes ARMv8.4-SecEL2. When supported, it is used when the value of SCR_EL3.EEL2 is 1.
b. The EL2&0 translation regime is supported only if an implementation includes ARMv8.1-VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

D5.2.3 Controlling address translation stages

The implemented Exception levels and the resulting translation stages and regimes on page D5-2396 defines the translation regimes and stages. For each supported address translation stages controlled from AArch64, Table D5-2 on page D5-2398 shows:

- A System register bit enables the stage of address translation, SCTLR_ELx.M or HCR_ELx.VM.
- A System register bit determines the endianness of the translation table lookups, SCTLR_ELx.EE.
- A Translation Control Register (TCR_ELx) controls the stage of address translation.
- If a stage of address translation supports two VA ranges then that stage of translation provides:
  - A single TCR_ELx.
  - A TTBR_ELx for each VA range. TTBR0_ELx points to the translation tables for the address range that starts at 0x0000000000000000 and TTBR1_ELx points to the translation tables for the address range that ends at 0xFFFFFFFFFFFFFFFF.
Otherwise, a stage of translation provides a single TCR_ELx and a single TTBR_ELx that holds the address of the translation table that must be used for the first lookup for the stage of address translation.

</tbody>
</table>

a. This translation regime is supported only if an implementation includes ARMv8.4-SecEL2. When supported, it is used when the value of SCR_EL3.EEL2 is 1.

b. The EL2&0 translation regime is supported only if an implementation includes ARMv8.1-VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

### Note

If the PA of the software that enables or disables a particular stage of address translation differs from its VA, speculative instruction fetching can cause complications. ARM strongly recommends that the PA and VA of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

The following subsections give more information about controlling address translation:

- *System registers relevant to MMU operation* on page D5-2399.
- *Address size configuration* on page D5-2399.
- *Atomicity of register changes on changing virtual machine* on page D5-2405.
- *Use of out-of-context translation regimes* on page D5-2406.
System registers relevant to MMU operation

In AArch64 state, System registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a Common abbreviation for each of the System registers that affects MMU operation, as Table D5-3 shows. The common abbreviation is used when describing features that apply to multiple translation regimes or stages.

--- Note ---
The only translation regime that supports a stage 2 translation is the EL1&0 translation regime, when EL2 is enabled.

<table>

*a. Only when both the implementation includes ARMv8.4-SecEL2 and the value of SCR_EL3.EEL2 is 1.

*b. Only when both the implementation includes ARMv8.1-VHE and the value of HCR_EL2.E2H is 1.

Address size configuration

The following subsubsections specify the configuration of the PA size and of the input and output address sizes for each of the stages of address translation:

- *Physical address size* on page D5-2400.
- *Output address size* on page D5-2400.
- *Input address size* on page D5-2401.
- *Supported IPA size* on page D5-2403.
**Physical address size**

The ID_AA64MMFR0_EL1.PARange field indicates the implemented PA size, as Table D5-4 shows.

<table>
<thead>
<tr>
<th>ID_AA64MMFR0_EL1.PARange</th>
<th>Total PA size</th>
<th>PA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>4 GB</td>
<td>32 bits, PA[31:0]</td>
</tr>
<tr>
<td>0001</td>
<td>64 GB</td>
<td>36 bits, PA[35:0]</td>
</tr>
<tr>
<td>0010</td>

</tr>
<tr>
<td>0101</td>
<td>256 TB</td>
<td>48 bits, PA[47:0]</td>
</tr>
<tr>
<td>0110</td>
<td>4PB</td>
<td>52 bits, PA[51:0]</td>
</tr>
</tbody>
</table>

*a.* Only when an implementation includes ARMv8.2-LPA and the 64KB translation granule is used, see *Extending addressing above 48 bits on page D5-2404.*

All other PARange values are reserved.

**Output address size**

For each enabled stage of address translation, TCR_ELx.{I}PS must be programmed to maximum output address size for that stage of translation, using the encodings as shown in Table D5-5.

<table>
<thead>
<tr>
<th>TCR_ELx.{I}PS</th>
<th>Total output size</th>
<th>Output address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>4 GB</td>
<td>32 bits, PA[31:0]</td>
</tr>
<tr>
<td>001</td>
<td>64 GB</td>
<td>36 bits, PA[35:0]</td>
</tr>
<tr>
<td>010</td>
<td>1 TB</td>
<td>40 bits, PA[39:0]</td>
</tr>
<tr>

<td>48 bits, PA[47:0]</td>
</tr>
<tr>
<td>110</td>
<td>4PB</td>
<td>52 bits, PA[51:0]</td>
</tr>
</tbody>
</table>

*a.* Only when an implementation includes ARMv8.2-LPA and is using the 64KB translation granule, see *Extending addressing above 48 bits on page D5-2404.*

---

**Note**

- The naming of this field is as follows:
  - **IPS**
    - In TCR_EL1.
    - In an implementation that includes ARMv8.1-VHE, in TCR_EL2 when the value of HCR_EL2.E2H is 1.
  - **PS**
    - Otherwise.
The {I}PS fields are 3-bit fields, corresponding to the least-significant PARange bits shown in Table D5-4 on page D5-2400.

If {I}PS is programmed to a value larger than the implemented PA size, then the PE behaves as if programmed with the implemented PA size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented PA size. Table D5-4 on page D5-2400 shows the implemented PA size.

The PE checks that the TTBR_ELx, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the TTBR_ELx is always reported as a level 0 fault. When ARMv8.2-LPA is implemented and a translation granule of 4KB or 16KB is in use, all output addresses are treated as having bits[51:48] set to 0b0000.

If stage 1 translation is disabled and the input address is larger than the implemented PA size, then a stage 1 level 0 Address size fault is generated.

**Note**

These faults are reported as level 0 faults even if they occur in a translation stage that does not perform level 0 lookups.

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented PA size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.
- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

**Input address size**

For each enabled stage of address translation, the TCR_ELx.TxSZ fields specify the input address size:

**For a stage of translation that can support two VA ranges**

The TCR_ELx has two TxSZ fields, corresponding to the two VA ranges:

- TCR_ELx.T0SZ specifies the size for the lower VA range, translated using TTBR0_ELx.
- TCR_ELx.T1SZ specifies the size for the upper VA range, translated using TTBR1_ELx.

**For a stage of translation that supports only a single input address (IA) range**

The TCR_ELx has a single T0SZ field, and IAs are translated using TTBR0_ELx.

Attempting to translate an address that is larger than the configured input address size generates a Translation fault. This means:

- For a TCR_ELx with a single T0SZ field and a 48-bit address size, Figure D5-2 on page D5-2402 shows the input address map:
For a TCR_ELx with two TxSZ fields, the input address is always a VA, and Selection between TTBR_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2429 describes the VA address map.

For the EL1&0 translation regime when EL2 is enabled, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ, then the input address size check for the stage 2 translation generates a Translation fault.

Although software can configure the input address size to be smaller than 48 bits, all implemented AArch64 TTBR_ELx must support input address sizes of up to 48 bits, and in an implementation that includes ARMv8.2-LV A, all TTBR_ELx must support input address sizes of up to 52 bits.

Overview of the VMSAv8-64 address translation stages on page D5-2415 gives more information about the relationship between the required input address size, the value of TxSZ, and the required initial lookup level, and how these are affected by the translation granule size. However:

For all translation stages

If ARMv8.4-TTST is implemented, while the PE is executing in AArch64 state and is using 4KB or 16KB translation granules, the maximum TxSZ value is 48.

If ARMv8.4-TTST is implemented, while the PE is executing in AArch64 state and is using 64KB translation granules, the maximum TxSZ value is 47.

If ARMv8.4-TTST is not implemented or while the PE is executing in AArch32 state, the maximum TxSZ value is 39.

If TxSZ is programmed to a value larger than the defined maximum then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to the maximum for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a Level 0 Translation fault for the stage of translation at which TxSZ is used.

For a stage 1 translation

The effective minimum value of TxSZ is 16 if ARMv8.2-LVA is not supported or if the translation granule that is in use is 4KB or 16KB in size. When ARMv8.2-LVA is supported, for the 64KB translation granule size only, the effective minimum value of TxSZ is 12.

If TxSZ is programmed to a value smaller than the effective minimum value, and if ARMv8.2-LVA is not supported, then it IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a stage 1 level 0 Translation fault.
If \( T_xSZ \) is programmed to a value smaller than the effective minimum value when ARMv8.2-LVA is supported, then any use of the \( T_xSZ \) value generates a stage 1 level 0 Translation fault.

For more information, see *Extending addressing above 48 bits* on page D5-2404.

**For a stage 2 translation**

*Supported IPA size* defines the effective minimum value of \( T0SZ \), that depends on the supported PA size, and also describes the possible effects of programming \( T0SZ \) to a value that is smaller than this effective minimum value.

**Supported IPA size**

When EL2 is enabled in the current Security state, for the EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation is specified by \( VTCR\_EL2\_T0SZ \) or \( VSTCR\_EL2\_T0SZ \). For more information, see *Input address size* on page D5-2401 and *Output address size* on page D5-2400.

The maximum IPA size is constrained by the implemented PA size that is specified by \( ID\_AA64MMFR0\_EL1\_PARange \), see *Physical address size* on page D5-2400.

The implemented PA size also constrains the value of \( VTCR\_EL2\_SL0 \) and \( VSTCR\_EL2\_SL0 \), that specifies the level of the initial lookup. \( SL0 \) also depends on the translation granule, as described in *Overview of the VMSAv8-64 address translation stages* on page D5-2415.

**Table D5-6** PA size implications for the \( VTCR\_EL2\_T0SZ, SL0 \) and \( VSTCR\_EL2\_T0SZ, SL0 \) fields

a. Only supported if ARMv8.4-TTST is implemented, while the PE is executing in AArch64 state.
b. Only supported if ARMv8.2-LPA is implemented, and the PE is using the 64KB translation granule size.

If \( VTCR\_EL2\_SL0 \) is programmed to represent an initial lookup level not shown in Table D5-6, or is programmed to a reserved value, then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

If \( VTCR\_EL2\_T0SZ \) is programmed to a value smaller than the effective minimum value shown in Table D5-6, and if ARMv8.2-LPA is not implemented, then the implementation consistently does one of the following:

- Treats the \( VTCR\_EL2\_T0SZ \) field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treats the \( VTCR\_EL2\_T0SZ \) field as being programmed to the effective minimum value for all purposes other than:
  - Reading back the value of the field.
  - Checking whether the value of \( VTCR\_EL2\_T0SZ \) is consistent with the value of \( VTCR\_EL2\_SL0 \).
D5.2 The VMSAv8-64 address translation system

• Generates a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

If T0SZ is programmed to a value smaller than the effective minimum value when ARMv8.2-LPA is supported, then any use of the T0SZ value generates a stage 2 level 0 Translation fault.

For more information, see Extending addressing above 48 bits.

--- Note ---

Programming VTCR_EL2.T0SZ to a value smaller than the effective minimum value shown in Table D5-6 on page D5-2403 can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

• The PA size, for a VMSAv8-64 stage 1 translation.
• 40 bits, for a VMSAv8-32 stage 1 translation.

---

Extending addressing above 48 bits

ARMv8.2 defines the following options for supporting 52-bit addressing:

**ARMv8.2-LVA**
Supports 52-bit VAs when using the 64KB translation granule. The maximum IPA and PA sizes remain 48-bit unless ARMv8.2-LPA is implemented.

**ARMv8.2-LPA**
Supports 52-bit IPAs and PAs when using the 64KB translation granule. The maximum VA size remains 48-bit unless ARMv8.2-LVA is implemented.

ARMv8.2-LPA and ARMv8.2-LVA can be implemented independently of each other.

When using the 64KB translation granule, ARMv8.2-LPA supports Block descriptors in level 1 translation tables. In this case, a block covers a 4TB address range.

In all cases, 52-bit address ranges are supported only when using the 64KB translation granule. Maximum address sizes when using the other translation granules remain 48-bit.

See Address size configuration on page D5-2399 for how to configure use of 52-bit VAs when an implementation includes ARMv8.2-LVA.

When using the 64KB translation granule, the 52-bit input address size is supported as follows:

• In an implementation that includes ARMv8.2-LVA, for stage 1 translations the minimum value of TCR_ELx.TnSZ field is 12.
  
  If TCR_ELx.TnSZ is programmed to a value less than 12, any use of the TCR_ELx.TnSZ bit generates a stage 1 level 0 Translation fault.

• In an implementation that includes ARMv8.2-LVA, for a stage 2 translation the effective minimum value of VTCR_EL2.T0SZ and VSTCR_EL2.T0SZ is 12.
  
  If VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ is programmed to a smaller value than the effective minimum size, then any use of a stage 2 translation generates a stage 2 level 0 Translation fault.

Table D5-24 on page D5-2436 shows the translation table descriptor addressing for each level of lookup when using the 64KB translation granule.

In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule:

• Bits[15:12] of each valid translation table descriptor hold bits[51:48] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation. If the implementation does not support 52-bit physical addresses, then it is IMPLEMENTATION DEFINED whether non-zero values for these bits generate an Address size fault. In this case, not generating an Address Size Fault is deprecated.

• For a stage 1 translation, bits[5:2] of TTBR0_ELx or TTBR1_ELx holds bits[51:48] of the address of the translation table to be used for the initial lookup of that translation regime. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.
• For a stage 2 translation, bits[5:2] of VTTBR_EL2 or VSTTBR_EL2 holds bits[51:48] of the address of the translation table to be used for the initial lookup of the stage 2 translation. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.

• The minimum alignment of a translation table containing fewer than eight entries is 64 bytes.

Note
This is because, when the OA space is more than 48 bits, TTBR_ELx[5:2] specifies bits[51:48] of the translation table base address, and a translation table of fewer than eight entries would require one or more bits of TTBR_ELx[5:2] to be RES0 if the table was aligned to its size.

For more information, see VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats on page D5-2444 and ARMv8 translation table level 3 descriptor formats on page D5-2447.

The ID_AA64MMFR2_EL1.VA field indicates the supported VA size. This field has the value 0x1 if the implementation includes ARMv8.2-LVA.

The ID_AA64MMFR0_EL1.PArange field indicates the supported PA and IPA size. This field has the value 0x6 if the implementation supports 52-bit PAs.

In addition to the System registers discussed in this subsection, the ARMv8.2-LPA and ARMv8.2-LVA features affect the following System registers that contain addresses:

• HPFAR_EL2.
• PAR_EL1.
• VBAR_EL1, VBAR_EL2, VBAR_EL3.
• DBGVR<n>_EL1.
• DBGVVR<n>_EL1.
• MDRAR_EL1.
• LOREA_EL1.
• LORSA_EL1.

The larger VA, IPA, and PA addresses also affect the following System instructions for TLB maintenance:

• TLBI IPAS2E1.
• TLBI IPAS2E1S.
• TLBI IPAS2LE1.
• TLBI IPAS2LE1S.

Atomcity of register changes on changing virtual machine

From the viewpoint of software executing at EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the EL1&0, when EL2 is enabled, translation regime. This means that all of the following registers must change atomically:

• The registers associated with the stage 1 translations:
  — MAIR_EL1 and AMAIR_EL1.
  — TTBR0_EL1, TTBR1_EL1, TCR_EL1, and CONTEXTIDR_EL1.
  — SCTLR_EL1.

• The registers associated with the stage 2 translations:
  — VTTBR_EL2 and VTCR_EL2.
  — SCTLR_EL2.

Note
Only some bits of SCTLR_EL1 affect the stage 1 translation, and only some bits of SCTLR_EL2 affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.
These registers apply to execution using the EL1&0, when EL2 is enabled, translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Similar considerations apply when ARMv8.1-VHE is implemented.

**Use of out-of-context translation regimes**

The architecture requires that:

- When executing at EL3, Secure or Non-secure EL2, or Secure EL1, the PE must not use the registers associated with the Non-secure EL1&0 translation regime for speculative memory accesses.
- When executing at EL3, Secure or Non-secure EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure EL1&0 translation regime for speculative memory accesses.
- When executing at EL3 or Non-secure EL1, the PE must not use the registers associated with the Secure EL2, or Secure EL2&0 translation regime for speculative memory accesses.
- When executing at EL3 or Secure EL1, the PE must not use the registers associated with the Non-secure EL2, or Non-secure EL2&0 translation regime for speculative memory accesses.
- When secure EL2 is not enabled, the PE must not use the registers associated with the Secure EL2, or Secure EL2&0 translation regime for speculative memory accesses.

When entering an Exception level, on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.

---

**Note**

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

---

**D5.2.4 Memory translation granule size**

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory page size. That is, the granularity of a translation table lookup.
VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB. Support for each granule size is optional, and is indicated as shown in Table D5-7:

<table>
<thead>
<tr>
<th>Granule size</th>
<th>Support indicated by:</th>
<th>Field Values</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN4</td>
<td>0b0000</td>
<td>4KB granule size supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b1111</td>
<td>4KB granule size not supported.</td>
</tr>
<tr>
<td>16KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN16</td>
<td>0b0000</td>
<td>16KB granule size not supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b0001</td>
<td>16KB granule size supported.</td>
</tr>
<tr>
<td>64KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN64</td>
<td>0b0000</td>
<td>64KB granule size supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b1111</td>
<td>64KB granule size not supported.</td>
</tr>
</tbody>
</table>

In VMSAv8-64, each address translation stage is configured, independently, to use one of the supported granule sizes.

Note
- Using a larger granule size can reduce the maximum required number of levels of address lookup because:
  - The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
  - The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.
- ARM recommends that memory-mapped peripherals are separated by an integer multiple of the largest granule size supported by the operating system or hypervisor, to allow each peripheral to be managed independently.

Table D5-8 summarizes the effects of the different granule sizes.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

How the granule size affects the address translation process
As Table D5-8 shows, the translation granule determines the number of address bits:
- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the input address (IA) is resolved to an output address (OA) by the translation process.
Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple levels of lookup.

Considering the resolution of an IA range of 48 bits, with a translation granule size of $2^n$ bytes:

- The least-significant $n$ bits of the IA address the memory page. This means $\text{OA}[n-1:0]=\text{IA}[n-1:0]$.
- The remaining $(48-n)$ bits of the IA, $\text{IA}[47:n]$, must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
  - A complete translation table holds $2^{(n-3)}$ descriptors.
  - A single level of translation can resolve a maximum of $(n-3)$ bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because the translation needs to resolve $\text{IA}[47:n]$ and a level of lookup can resolve $(n-3)$ bits of address:

- The final level of lookup resolves $\text{IA}[2n-4:n]$.
- The previous level of lookup resolves $\text{IA}[3n-7:(2n-3)]$.

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, for a 48-bit IA the address bits resolved in a level of lookup are:

$$\text{IA}[\text{Min}(47, ((m-3)(n-3)+2n-4)):\text{Min}(n+3, (n-3))]$$

where:

- $\text{Min}(a, b)$ is a function that returns the minimum of $a$ and $b$.
- $m$ indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

The following diagrams show this model, for each of the permitted granule sizes.

Figure D5-3 shows how a 48-bit IA is resolved when using the 4KB translation granule.

Figure D5-3 How a 48-bit IA is resolved when using the 4KB translation granule

Figure D5-4 on page D5-2409 shows how a 48-bit IA is resolved when using the 16KB translation granule.
Figure D5-4 How a 48-bit IA is resolved when using the 16KB translation granule

Figure D5-5 shows how a 48-bit IA is resolved when using the 64KB translation granule.

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule:

- The IA range that can be addressed by the level 1 lookup is IA[51:42].
- The level 1 lookup can directly address a block of memory, returning OA[51:42].

--- Note

The increased IA range means the size of the indexed level 1 translation table is increased.

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.
Effect of granule size on translation table addressing and indexing

Table D5-9 shows the effect of the translation granule size on the addressing and indexing of the TTBR_ELx, and on the input address range that must be resolved.

</table>

* a. Smaller value than indicated in Table D5-9, as explained in this section.
* b. Level 0 lookup not possible with 64KB granule size
* c. The second entry applies to an implementation that includes ARMv8.2-LVA and has selected an IA space larger than 47 bits, see Extending addressing above 48 bits on page D5-2404. The first entry applies otherwise.

Table D5-9 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in Table D5-9:

Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

**Note**

— This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
— For a stage 2 translation, it might be possible to start the translation at a lower level, see Concatenated translation tables.

- More low-order TTBR_ELx bits are needed to hold the translation table base address.

Example D5-1 shows how this applies to translating a 35-bit input address range using the 4KB granule.

**Example D5-1 Effect of an IA width of 35 bits when using the 4KB granule size**

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, IA[34:0], Table D5-10 on page D5-2410 shows that lookup must start at level 1, and that the initial lookup must resolve IA[34:30], meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by $2^4$, giving a size of 256B.
- The TTBR_ELx requires 4 more bits for the translation table base address, which becomes TTBR_ELx[47:8].

When using the 64KB translation granule to translate the maximum IA size of 48 bits, Table D5-10 on page D5-2410 shows that a level 1 lookup must resolve only IA[47:42]. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by $2^7$, giving a size of 512B.
- The TTBR_ELx requires 7 more bits for the translation table base address, which becomes TTBR_ELx[47:9].

**Concatenated translation tables**

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. The block of concatenated translation tables must be aligned to the size of the block of translation tables.

This means that each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional $n$ bits requires $2^n$ concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the TTBR_ELx.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in Table D5-10 on page D5-2410 can be extended by up to 4 bits. Example D5-2 shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

**Example D5-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule**

Table D5-10 on page D5-2410 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The TTBR_ELx requires 1 fewer bit for the translation table base address, which becomes TTBR_ELx[47:13].

For more information, see Use of concatenated translation tables for the initial stage 2 lookup on page D5-2431.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.
The translation table base address held in the TTBR_ELx is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has the maximum OA size, meaning the translation table base address is:

- **TTBR_ELx[47:12]** if using the 4KB translation granule.
- **TTBR_ELx[47:14]** if using the 16KB translation granule.
- **TTBR_ELx[47:16]** if using the 64KB translation granule with an OA of 48 bits.
- In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule, OA[51:16], where:
  - **TTBR_ELx[5:2]** holds OA[51:48].
  - **TTBR_ELx[47:16]** holds OA[47:16].

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
  - **TTBR_ELx[47:40]** must be set to zero.
  - **TTBR_ELx[39:12]** holds the translation table base address.
- If using the 16KB translation granule:
  - **TTBR_ELx[47:40]** must be set to zero.
  - **TTBR_ELx[39:14]** holds the translation table base address.
- If using the 64KB translation granule:
  - **TTBR_ELx[47:40]** must be set to zero.
  - **TTBR_ELx[39:16]** holds the translation table base address.

In all cases, if **TTBR_ELx[47:40]** is not zero, any attempt to access the translation table generates an Address size fault.

### D5.2.5 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- **Translation table walks.**
- **Ordering of memory accesses from translation table walks** on page D5-2414.
- **Security state of translation table lookups** on page D5-2415.
- **Control of translation table walks** on page D5-2415.

See also **Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported** on page D5-2429.

#### Translation table walks

A *translation table walk* comprises one or more *translation table lookups*. The translation table walk is the set of lookups that are required to translate the VA to the PA. For the EL1&0, when EL2 is enabled, translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation, but *translation table walk* can also be used to refer to either:

- The set of lookups required for the stage 1 translation, that translates the VA to the IPA. This is the *stage 1 translation table walk*.
- The set of lookups required for the stage 2 translation, that translates the IPA to the PA. This is the *stage 2 translation table walk*.

The information returned by a successful translation table walk is:

- The required PA. If the access is from Secure state this includes identifying whether the access is to the Secure PA space or the Non-secure PA space, see **Security state of translation table lookups** on page D5-2415.
The memory attributes for the target memory region, as described in Memory types and attributes on page B2-122. For more information about how the translation table descriptors specify these attributes see Memory region attributes on page D5-2476.

The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see Memory access control on page D5-2456.

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR_ELx for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
  - The descriptor provides hierarchical attributes that are applied to the final translation, see Hierarchical control of Secure or Non-secure memory accesses on page D5-2455 and Hierarchical control of data access permissions on page D5-2460.
  - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

Figure D5-6 gives a generalized view of a single stage of address translation where three levels of lookup are required.

![Figure D5-6 Generalized view of a stage of address translation](image)

A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness. SCTLR_ELx.EE determines the endianness of the translation table lookups.

**Note**

Dynamically changing translation table endianness

Because any change to an SCTLR_ELx.EE, bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.
Address translation stages are disabled by setting an `SCTLR_ELx.M` bit or the `HCR_EL2.VM` bit to 0. See the appropriate register description for more information.

The appropriate `TTBR_ELx` holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than EL1&0, when EL2 is enabled, stage 1 translations, the output address held in the `TTBR_ELx`, and any translation table base address returned by a translation table descriptor, is the PA of the base of the translation table.

- For EL1&0, when EL2 is enabled, stage 1 translations, the output address held in the `TTBR_ELx`, and any translation table base address returned by a translation table descriptor, is the IPA of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

**Note**

TLB caching can be used to minimize the number of translation table lookups that must be performed. For the EL1&0, when EL2 is enabled, translation regime, because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a VA to PA address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

\[(S1+1)*(S2+1) - 1\]

Where, for this translation regime, S1 is the number of levels of lookup required for a stage 1 translation, and S2 is the number of levels of lookup required for a stage 2 translation.

The `TTBR_ELx` also determines the memory cacheability and shareability attributes that apply, for the corresponding stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

**Note**

- In a two stage translation regime, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see *Stage 2 fault on a stage 1 translation table walk* on page D5-2505.

- The rules about mismatched attributes given in *Mismatched memory attributes* on page B2-132 apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the `TCR_ELx` applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see *Overview of the VMSAv8-64 address translation stages* on page D5-2415.

See also *Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported* on page D5-2429.

**Ordering of memory accesses from translation table walks**

A translation table walk is considered to be a separate observer, and:

- A write to the translation tables can be observed by that separate observer at any time after the execution of the instruction that performed that write, but is only guaranteed to be observable after the execution of a D58 instruction by the PE that executed the instruction that performed that write to the translation tables.

- Any writes to the translation tables are not seen by any explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.
Security state of translation table lookups
For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.
For a Secure translation regime, the initial translation table lookup is performed to a Secure output address.
If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.
This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

Control of translation table walks
When stage 1 translations of a translation can support two V A ranges the TCR_ELx.{EPD0, EPD1} bits determine whether, for that regime, the two sets of translation tables for stage 1 are valid. EPD0 indicates whether the tables that TTBR0_ELx points to is valid, and EPD1 indicates whether the tables that TTBR1_ELx points to is valid. The effect of these bits is:
EPDn == 0 The translation tables are valid, and can be used for a translation table lookup.
EPDn == 1 If a TLB miss occurs based on TTBR_ELx, a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

D5.2.6 Overview of the VMSAv8-64 address translation stages
As shown in Memory translation granule size on page D5-2406, the granule size determines significant aspects of the address translation process. Effect of granule size on translation table addressing and indexing on page D5-2410 shows, for each granule size:
- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in Concatenated translation tables on page D5-2411.
- The TTBR_ELx addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:
- Overview of VMSAv8-64 address translation using the 4KB translation granule.
- Overview of VMSAv8-64 address translation using the 16KB translation granule on page D5-2418.
- Overview of VMSAv8-64 address translation using the 64KB translation granule on page D5-2423.

Overview of VMSAv8-64 address translation using the 4KB translation granule
The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.
Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR_ELx.TnSZ field. When using the 4KB translation granule, Table D5-11 shows this requirement.

Table D5-11 TCR_ELx.TnSZ values and IA ranges, 4KB granule with no concatenation of tables

<sup>a</sup> The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

<sup>b</sup> If ARMv8.4-TTST is not implemented, or while the PE is executing in AArch32 state, TnSZmax is 39.

<sup>c</sup> Only available if ARMv8.4-TTST is implemented, while the PE is executing in AArch64 state.

These configuration options are also permitted for stage 2 translations.

Note

Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

Figure D5-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

Figure D5-7 General view of VMSAv8-64 stage 1 address translation, 4KB granule
Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see *Use of concatenated translation tables for the initial stage 2 lookup* on page D5-2431.

When using the 4KB translation granule, Table D5-12 shows all possibilities for the initial lookup for a stage 2 translation.

</tr>
</tbody>
</table>

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.T0SZ, SL0 values. Table D5-12 shows the permitted T0SZ values for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

Figure D5-8 on page D5-2418 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. For an input address size in this range, the lookup can start at either level 0 or level 1.
VTCR_EL2.SL0 defines the start level.

</tr>
<tr>
<td>3</td>
<td>39</td>
<td>IA[24:14]</td>
<td>48(^a)</td>
<td>IA[15:14]</td>
</tr>
</tbody>
</table>

\(^a\) The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

\(^b\) If ARMv8.4-TTST is not implemented, the maximum is 39.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

— Note —

• When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.

• Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

Figure D5-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.
Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Use of concatenated translation tables for the initial stage 2 lookup on page D5-2431.

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.

When using the 16KB translation granule, Table D5-14 shows all possibilities for the initial lookup for a stage 2 translation.

Table D5-14 VTCR_EL2.T0SZ values and IA ranges, 16KB granule with possible concatenation of translation tables

<table>
<thead>
<tr>
<th>Tables a</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial lookup level (SL0 value)</td>
<td>T0SZ</td>
<td>IA</td>
<td>T0SZ</td>
<td>IA</td>
<td>T0SZ</td>

<tr>
<td>1 (2)</td>
<td>17-27</td>
<td>IA[46:14]-IA[36:14]</td>
<td>16</td>
<td>IA[47:14]</td>
<td>-</td>
</tr>
</tbody>
</table>

Note:
- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. Table D5-14 shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D5-10 on page D5-2421 shows the translation for this case.
However, for an input address size of between 37 and 40 bits, Table D5-14 on page D5-2420 shows that translation can start with either a level 1 lookup or a level 2 lookup, and Figure D5-11 on page D5-2422 shows these options.
VTTR_EL2 defines the start level.

a. The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.
b. Supported only if ARMv8.2-LVA is implemented and the 64KB translation granule is used, see Extending addressing above 48 bits on page D5-2404.
c. If ARMv8.4-TTST is not implemented or while the PE is executing in AArch32 state, the maximum value of TnSZ is 39 with IA[24:16].

These configuration options are also permitted for stage 2 translations.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.
- When ARMv8.2-LPA is implemented, a level 1 block attribute is supported when using the 64KB granule.

Figure D5-12 on page D5-2424 shows the stage 1 address translation, for an address translation using the 64KB granule with an input address size greater than 42 bits.
Figure D5-12 General view of VMSAv8-64 stage 1 address translation, 64KB granule with 52-bit VA support

Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Use of concatenated translation tables for the initial stage 2 lookup on page D5-2431.

When using the 64KB translation granule, Table D5-16 shows all possibilities for the initial lookup for a stage 2 translation.

Table D5-16 VTCR_EL2.T0SZ values and IA ranges, 64KB granule with possible concatenation of translation tables

<table>
<thead>
<tr>

<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

\(^a\) Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in Table D5-15 on page D5-2423.

\(^b\) The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.
c. Only supported if the PA size is 52 bits, see Extending addressing above 48 bits on page D5-2404.

d. If ARMv8.4-TTST is not implemented or while the PE is executing in AArch32 state, the maximum T0SZ value is 39, with IA[24:16].

--- Note ---

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. Table D5-16 on page D5-2424 shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

Figure D5-13 shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

VTCR_EL2.SL0 defines the start level.

Figure D5-13 General view of VMSAv8-64 stage 2 address translation, 64KB granule
D5.2.7 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64. For these translation regimes:

For a stage 1 translation that can support two VA ranges

- For the lower VA range, that uses TTBR0_ELx:
  - The TCR_ELx.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
  - The TCR_ELx.TG0 field defines the Translation granule size.
- For the upper VA range, that uses TTBR1_ELx:
  - The TCR_ELx.{SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walks.
  - The TCR_ELx.TG1 field defines the Translation granule size.
- Each of TTBR0_ELx and TTBR1_ELx contains an ASID field, and the TCR_ELx.A1 field selects which of these specifies the ASID to use.

For a stage 1 translation that supports only one VA range

The translation table walks use TTBR0_ELx, and:

- The TCR_ELx.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The TCR_ELx.TG0 field defines the Translation granule size.

For a stage 2 translation

The Non-secure translation table walks use VTTBR_EL2, and:

- The VTCR_EL2.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The VTCR_EL2.TG0 field defines the Translation granule size.

The Non-secure translation table walks use VTTBR_EL2, and:

- The VTCR_EL2.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The VTCR_EL2.TG0 field defines the Translation granule size.

The Secure translation table walks use VSTTBR_EL2, and:

- The VSTCR_EL2.SH0 and VTCR_EL2.{ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The VSTCR_EL2.TG0 field defines the Translation granule size.

The Secure translation table walks use VSTTBR_EL2, and:

- The VSTCR_EL2.SH0 and VTCR_EL2.{ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The VSTCR_EL2.TG0 field defines the Translation granule size.

For the VMSAv8-64 translation table format, Overview of the VMSAv8-64 address translation stages on page D5-2415 summarizes the lookup levels, and Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats on page D5-2446 describes the translation table entries.

The following subsections describe the use of this translation table format:

- Translation granule size and associated block and page sizes on page D5-2427.
- Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D5-2429.
- Use of concatenated translation tables for the initial stage 2 lookup on page D5-2431.
- Possible errors in programming the translation table registers on page D5-2432.
Translation granule size and associated block and page sizes

Table D5-17 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

Table D5-17 Translation granule sizes, with block and page sizes, and output address ranges

</tbody>
</table>

a. Only available when ARMv8.2-LPA is implemented, see Extending addressing above 48 bits on page D5-2404.

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:

- The 4KB granule size supports block descriptors only in level 1 and level 2 translation tables.
- The 16KB granule size supports block descriptors only in level 2 translation tables.
- The 64KB granule size supports block descriptors in level 2 translation tables, and in level 1 translation tables when ARMv8.2-LPA is implemented and the implementation supports 52 bits of physical address. If the implementation does not support 52 bits of physical address, then encoding a block descriptor in a level 1 translation table generates a level 1 Translation fault.

If bit[1] of a descriptor is 0 in a translation table that does not support block descriptors then a translation table walk that accesses that descriptor generates a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for an access to a single translation table at each lookup level:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D5-18 on page D5-2428 shows this information for the 4KB translation granule size, Table D5-19 on page D5-2428 shows this information for the 16KB translation granule size, and Table D5-20 on page D5-2428 shows this information for the 64KB translation granule size.
### Table D5-18 Properties of the address lookup levels, 4KB granule size

<td>4TB Address[41:29]</td>
<td>Address[47:29] 512MB</td>
<td>Up to 8192</td>
<td>Yes</td>
</tr>
<tr>
<td>Three</td>
<td>512MB Address[28:16]</td>
<td>Address[47:16] 64KB</td>
<td>8192</td>
<td>Page only</td>
</tr>
</tbody>
</table>

- a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
- b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

For the initial lookup level:

- If the IA range specified by the TCR_ELx.TxSZ field is smaller than the maximum size shown in these tables, then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.
For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in *Overview of the VMSAv8-64 address translation stages on page D5-2415* and *Use of concatenated translation tables for the initial stage 2 lookup on page D5-2431.*

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

---

**Note**

Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of VA.

---

For the TCR_ELx programming requirements for the initial lookup, see *Overview of the VMSAv8-64 address translation stages on page D5-2415.*

**Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported**

Every translation table walk starts by accessing the translation table addressed by the TTBR_ELx for the stage 1 translation for the required translation regime.

For a stage 1 translation that can support two VA ranges, Figure D5-14 shows this VA range split when using 48-bit VAs, and:

- **TTBR0_ELx** points to the initial translation table for the lower VA range, that starts at address 0x0000000000000000,
- **TTBR1_ELx** points to the initial translation table for the upper VA range, that runs up to address 0xffffffffffffff.

As Figure D5-14 shows, for 48-bit VAs:

- The address range translated using TTBR0_ELx is 0x0000000000000000 to 0x0000ffffffffff.
- The address range translated using TTBR1_ELx is 0xffff000000000000 to 0xffffffffffffff.

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, for 52-bit VAs:

- The address range translated using TTBR0_ELx is 0x0000000000000000 to 0x0000000000000000.
- The address range translated using TTBR1_ELx is 0xffffff0000000000 to 0xffffffffffffff.

Which TTBR_ELx is used depends only on the VA presented for translation. The most significant bits of the VA must all be the same value and:

- If the most significant bits of the VA are zero, then TTBR0_ELx is used.
- If the most significant bits of the VA are one, then TTBR1_ELx is used.
However, it is configurable whether VA[63:56] are considered when determining which TTBR_ELx is used, that is:

- In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, whether the determination depends on VA[63:52] or on VA[55:52].
- Otherwise, whether the determination depends on VA[63:48] or on VA[55:48].

For more information about whether VA[63:56] are considered for this determination see Address tagging in AArch64 state on page D5-2386.

--- Note ---

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the TCR_ELx.TnSZ values and the region for which an access generates a Translation fault is wider than shown in Figure D5-14 on page D5-2429. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. Possible errors in programming the translation table registers on page D5-2432 describes this possibility.

Example D5-3 shows a typical application of this VA split.

**Example D5-3 Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls**

An example of using the split VA range is:

**TTBR0_ELx** Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0_ELx is updated to point to the level 1 translation table for the new context
- TCR_ELx is updated if this change changes the size of the translation table
- CONTEXTIDR_ELx is updated.

**TTBR1_ELx** Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is \(2^{(64-TnSZ)}\), where TnSZ is one of TCR_ELx.\{T0SZ, T1SZ\},

This means the two VA subranges are:

**Lower VA subrange** \(0x0000_0000_0000_0000\) to \(2^{(64-T0SZ)} - 1\).

**Upper VA subrange** \(2^{64} - 2^{(64-T1SZ)}\) to \(0xFFFF_FFFF_FFFF_FFFF\).

For the situation where the minimum TnSZ value is 16, corresponding to a maximum input address range of 48 bits, Example D5-4 shows the two VA subranges when T0SZ and T1SZ are both set to this minimum value.

---

**Example D5-4 Maximum VA ranges when a stage of translation supports two ranges**

The maximum VA subranges correspond to T0SZ and T1SZ each having a minimum value of 16. In this case the subranges are:

**Lower VA subrange** \(0x0000_0000_0000_0000\) to \(0x0000_FFFF_FFFF_FFFF\).

**Upper VA subrange** \(0xFFFF_0000_0000_0000\) to \(0xFFFF_FFFF_FFFF_FFFF\).

---

Figure D5-14 on page D5-2429 indicates the effect of varying the TnSZ values.

As described in Overview of the VMSAv8-64 address translation stages on page D5-2415, the TnSZ values also determine the initial lookup level for the translation.
Use of concatenated translation tables for the initial stage 2 lookup

*Overview of the VMSAv8-64 address translation stages on page D5-2415* introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

When using the 16KB translation granule, if a 48-bit input address size is required for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program VTTBR_EL2 or VSTTBR_EL2 to hold the address of the first of the concatenated translation tables.
- Program VTCR_EL2 or VSTCR_EL2 to indicate the required input address range and initial lookup level.

--- Note ---
The use of concatenated translation tables avoids the overhead of an additional level of translation.

Concatenating additional translation tables at the initial level of lookup resolves additional address bits at that level. To resolve $n$ additional address bits requires $2^n$ concatenated translation tables. *Example D5-5* shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

### Example D5-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires $2^3$ translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is $8 \times 4\text{KB} = 32\text{KB}$.
- This block of concatenated translation tables must be aligned to 32KB.
- The address range resolved at this lookup level is A[41:30], of which:
  - Bits A[41:39] select the 4KB translation table.
  - Bits A[38:30] index a descriptor within that translation table.

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, *Table D5-21* shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1 with a single translation table at that level.

### Table D5-21 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule

<table>
<thead>
<tr>
<th>IPA range</th>
<th>Size</th>
<th>Lookup starts at level 0</th>
<th>Lookup starts at level 1</th>
<th>Required alignment(^a)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPA[38:0]</td>
<td>$2^{36}$ bytes</td>
<td>-</td>
<td>1</td>
<td>4KB</td>
</tr>
<tr>
<td>IPA[39:0]</td>
<td>$2^{37}$ bytes</td>
<td>2</td>
<td>2</td>
<td>8KB</td>
</tr>
</tbody>
</table>

---

\(^a\) Required alignment is the alignment of the block of concatenated translation tables.
Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are IPAs.

### Possible errors in programming the translation table registers

This subsection describes possible errors in programming the translation table registers.

#### Misprogramming the VTCR_EL2.(T0SZ, SL0) and VSTCR_EL2.(T0SZ, SL0) fields

For a stage 2 translation, the programming of the VTCR_EL2 or VSTCR_EL2 T0SZ and SL0 fields must be consistent. If these fields are not consistent, or if SL0 is programmed to a reserved value, any translation table walk that uses stage 2 translation generates a stage 2 level 0 Translation fault. For more information see *Overview of the VMSAv8-64 address translation stages* on page D5-2415.

#### Misprogramming of the Contiguous bit

For more information about the Contiguous bit, and the range of translation table entries that must have the bit set to 1 to mark the entries as contiguous, see *The Contiguous bit on page D5-2481*.

If one or more of the following errors is made in programming the translation tables, the TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
- One or more of the contiguous translation table entries holds an output address that is not consistent with all of the entries pointing to the same aligned contiguous address range.
- The attributes and permissions of the contiguous entries are not all the same.

Such misprogramming of the translation tables means the output address, memory permissions, or attributes for a lookup might be corrupted, and might be equal to values that are not consistent with any of the programmed translation table values.

In some implementations, such misprogramming might also give rise to a TLB Conflict abort.

The architecture guarantees that misprogramming of the Contiguous bit cannot provide a mechanism for any of the following to occur:

- Software executing at EL1 or EL0 accessing regions of physical memory that are not accessible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing at EL1 or EL0 accessing regions of physical memory with attributes or permissions that are not possible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.

---

#### Table D5-21 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule (continued)

<table>
<thead>
<tr>
<th>IPA range</th>
<th>Configured stage 2 IA size</th>
<th>Lookup starts at level 0</th>
<th>Lookup starts at level 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPA[40:0]</td>
<td>2^{38} bytes</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>IPA[41:0]</td>
<td>2^{39} bytes</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>IPA[42:0]</td>
<td>2^{40} bytes</td>
<td>16</td>
<td>16</td>
</tr>
</tbody>
</table>

a. Required alignment of the set of concatenated level 2 tables.
Software executing in Non-secure state accessing Secure physical memory.

**Note**

Hardware implementations must ensure that use of the Contiguous bit cannot provide a mechanism for avoiding output address range checking. This might occur if a Contiguous bit block size of 0.5GB or 1GB is used in a system with the output address size configured to 4GB. The architecture permits the implemented mechanism for preventing any avoidance of output address range checking to suppress the use of the Contiguous bit for such entries in such a system.

Where the Contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the TCR_ELx.TxSZ field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the TCR_ELx.TxSZ field.

- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the TCR_ELx.TxSZ field, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

When ARMv8.2-LVA is implemented, level 1 block descriptors for the 64KB granule do not support the Contiguous bit, and that field is RES0.

**D5.2.8 The algorithm for finding the translation table descriptors**

This subsection gives the algorithms for finding the translation table descriptor that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- *Finding the translation table descriptor when using the 4KB translation granule* on page D5-2434.
- *Finding the translation table descriptor when using the 16KB translation granule* on page D5-2435.
- *Finding the translation table descriptor when using the 64KB translation granule* on page D5-2436.

Each subsection uses the following terms:

**BaseAddr**

The base address for the level of lookup, as defined by:

- For the initial lookup level, the value of the appropriate TTBR_ELx.BADDR field.
- Otherwise, the translation table address returned by the previous level of lookup.

**PAMax**

The supported PA width, in bits.

**IA**

The supplied IA for this stage of translation.

**TnSZ**

The translation table size for this stage of translation:

For **EL1&0 stage 1**

TCR_EL1.T0SZ or TCR_EL1.T1SZ, as appropriate.

For **Non-secure EL1&0 stage 2**

VTCR_EL2.T0SZ.

For **Secure EL1&0 stage 2**

VSTCR_EL2.T0SZ.

For **EL2 stage 1**

TCR_EL2.T0SZ.

For **EL2&0 stage 1**

TCR_EL2.T0SZ or TCR_EL2.T1SZ, as appropriate.
For EL3 stage 1  

TCR_EL3.T0SZ.

SL0  
The initial lookup level for this stage of translation:

For Non-secure EL1&0 stage 2 translation  

VTCR_EL2.SL0  

For Secure EL1&0 stage 2 translation  

VSTCR_EL2.SL0

These subsections show only architecturally-valid programming of the TCR_ELx. See also *Possible errors in programming the translation table registers* on page D5-2432.

Finding the translation table descriptor when using the 4KB translation granule

Table D5-22 shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D5-2433 for more information about terms used in the table.

c. $SL0 == 0$ if the initial lookup is level 3, $SL0 == 1$ if the initial lookup is level 2, and $SL0 == 2$ if the initial lookup level is at level 1.

d. This is the case where this level of lookup is not the initial level of lookup.

Table D5-7 on page D5-2407 shows how software can determine whether an implementation supports the 64KB granule size.
D5.2.9 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- Behavior when stage 1 address translation is disabled.
- Behavior when stage 2 address translation is disabled on page D5-2438.
- Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2438.

Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

EL1 and EL0 accesses if the HCR_EL2.DC bit is set to 1

For the EL1&0, when EL2 is enabled, translation regime, when the value of HCR_EL2.DC is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

Note

This applies for both instruction and data accesses.

All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the SCTLR_ELx.I bit for the translation regime, as follows:

When the value of I is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

When the value of I is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed. Therefore no MMU faults can be generated for this stage of address translation.

Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of HCR_EL2.DC is 1:

- The SCTLR_EL1.M bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means EL1&0 stage 1 address translation is disabled.
- The HCR_EL2.VM bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that EL1&0 stage 2 address translation is enabled.

See also Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2438.
Effect of disabling address translation on maintenance and address translation instruction instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of HCR_EL2.DC affect some address translation instructions, see Address translation instructions, AT* on page D5-2440.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

• The IPA output from the stage 1 translation maps flat to the PA.
• The memory attributes and permissions from the stage 1 translation apply to the PA.

When both stages of address translation are disabled, see also Behavior of instruction fetches when all associated stages of translation are disabled.

Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:

• The Secure EL1&0, when EL2 is disabled, translation regime when stage 1 address translation is disabled in that regime.
• The EL3 translation regime when stage 1 address translation is disabled in that regime.
• The Secure EL2, or Secure EL2&0, translation regime when stage 1 address translation is disabled in that regime.
• The Non-secure EL1&0, when EL2 is enabled, translation regime, when both stages of address translation are disabled.

Note

• The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
• When the value of HCR_EL2.DC is 1, then the behavior of the EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in Behavior when stage 1 address translation is disabled on page D5-2437.

In these cases, when execution is in AArch64 state, a memory location might be accessed as a result of an instruction fetch if either:

• The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset.

• The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  — The last reset.
  — The last synchronization of instruction cache maintenance targeting the address of the branch instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.
Note

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
- Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D5.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections outline a pseudocode description of the translation table walk:

- Definitions required for address translation.
- Performing the full address translation.
- Stage 1 translation.
- Stage 2 translation.
- Translation table walk.
- Support functions on page D5-2440.

Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a TLBRecord structure. Memory data type definitions on page D4-2380 includes definitions of the Permissions and AddressDescriptor parameters.

Performing the full address translation

The function AArch64.FullTranslate() performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied VA, and for the EL1&0, when EL2 is enabled, translation regime it then performs a stage 2 translation of the returned address.

Stage 1 translation

The function AArch64.FirstStageTranslate() performs a stage 1 translation, calling the function AArch64.TranslationTableWalk(), described in Translation table walk, to perform the required translation table walk. However, if stage 1 translation is disabled, it calls the function AArch64.TranslateAddressS1Off() to set the memory attributes.

Stage 2 translation

In the EL1&0, when EL2 is enabled, translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. Function AArch64.SecondStageTranslate() performs this translation, by calling the AArch64.SecondStage translate() function. When called from AArch64.SecondStageWalk(), the AArch64.SecondStageTranslate() function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section.

Translation table walk

The function AArch64.TranslationTableWalk() returns the result, in the form of a TLBRecord, of a translation table walk made for a memory access from an Exception level that is using AArch64.
Support functions

In the translation table walk functions, the \texttt{WalkAttrDecode()} function determines the attributes for a translation table lookup.

The function \texttt{AArch64.S1AttrDecode()} decodes the attributes from a stage 1 translation table lookup.

The function \texttt{AArch64.CheckPermission()} checks the access permissions returned by a stage 1 translation table lookup, see \textit{Access permission checking} on page D4-2382.

The function \texttt{AArch64.CheckS2Permission()} checks the access permissions returned by a stage 2 translation table lookup.

The function \texttt{AddrTop()} returns the bit number of the most significant valid bit of a VA in the current translation regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

D5.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

\textit{Address translation instructions, AT*} summarizes the A64 address translation instructions.

See also \textit{A64 System instructions for address translation} on page C5-452.

Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

\texttt{AT <operation>, <Xt>}

Where:

\texttt{<operation>} is one of \texttt{S1E1R}, \texttt{S1E1RP}, \texttt{S1E1W}, \texttt{S1E0R}, \texttt{S1E0W}, \texttt{S1E0R}, \texttt{S1E0W}, \texttt{S1E2R}, \texttt{S1E2W}, \texttt{S12E1R}, \texttt{S12E1W}, \texttt{S12E0R}, \texttt{S12E0W}, \texttt{S12E0R}, \texttt{S12E0W}, \texttt{S12E3R}, or \texttt{S12E3W}.

\texttt{<operation>} has a structure of \texttt{<stages><level><read|write><pan>}, where:

\texttt{<stages>} is one of:

- \texttt{S1} Stage 1 translation.
- \texttt{S12} Stage 1 translation followed by stage 2 translation.

\texttt{<level>} describes the Exception Level that the translation applies to. Is one of:

- \texttt{E0} EL0.
- \texttt{E1} EL1.
- \texttt{E2} EL2.
- \texttt{E3} EL3.

If \texttt{<level>} is higher than the current Exception Level, the instruction is \texttt{UNDEFINED}.

\texttt{<read|write>} is one of:

- \texttt{R} Read.
- \texttt{W} Write.

\texttt{<pan>} Only available when ARMv8.2-ATS1E1 is implemented. Optional, but if present:

- \texttt{P} Determines action based on value of \texttt{PSTATE.PAN}.

Only permitted for \texttt{<stages>=S1} and \texttt{<level>=E1}. 

The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

--- Note ---

If EL2 is not implemented but EL3 is implemented, the AT S12E** instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E** instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see Synchronous faults generated by address translation instructions.

--- Note ---

The architecture provides a single PAR, PAR_EL1, that is used regardless of:

- The Exception level at which the instruction was executed.
- The Exception level that controls the stage or stages of translation used by the instruction.

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

If EL3 is implemented, then for instructions that apply to the EL1 or EL0 Exception level, SCR_EL3.NS determines the translation regime to which the instruction applies, as follows:

- **SCR_EL3.NS == 0** Secure EL1&0 translation regime.
- **SCR_EL3.NS == 1** Non-secure EL1&0 translation regime.

All relevant context information used for the translation depends on this determination.

When EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S12E0*, or AT S12E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR_EL2.DC bit as described in Behavior when stage 1 address translation is disabled on page D5-2437.

If Secure EL2 translation regime is disabled, executing AT S1E2R or AT S1E2W at EL3 with **SCR_EL3.NS == 0** is UNDEFINED.

--- Note ---

AT S12E** instructions at EL3 with **SCR_EL3.NS == 0** are not UNDEFINED but behave the same way as the equivalent AT S1E** instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
• Synchronous External aborts during a translation table walk.

In addition:

• If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.

• For a stage 1 translation for the EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see Stage 2 fault on a stage 1 translation table walk on page D5-2505.

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the PAR_EL1.FST field holds the Fault status information. In these cases the PAR_EL1.PA field does not hold the output address of the translation.

The exceptions to this reporting the fault in PAR_EL1 are:

• Synchronous External aborts during a translation table walk are taken as a Data Abort exception.

For an address translation instruction executed at a particular Exception level, if the synchronous External abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

If the synchronous External abort is generated on a stage 2 translation table walk then:

— If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.

— If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

— The PAR_EL1 is UNKNOWN.

— The ESR_ELx of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.

— The FAR_ELx of the target Exception Level holds the VA for the translation request.

• For the AT S1E0* and AT S1E1* instructions executed from EL1, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then if the value of SCR_EL3.EA is 1 then a synchronous External abort on a stage 2 translation table walk is taken to EL3. In all other cases of a synchronous stage 2 fault on a memory access made as part of the translation table walk, the fault is taken as an exception to EL2, and:

— PAR_EL1 is UNKNOWN

— ESR_EL2 indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.

— HPFAR_EL2 holds the IPA that faulted

— FAR_EL2 holds the VA that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

— Stage 2 Translation fault.

— Stage 2 Access fault.

— Stage 2 Permission fault.

— Stage 2 Address size fault.

— Synchronous External abort on a stage 2 translation table walk.

**Synchronization requirements of the address translation instructions**

Where an instruction results in an update to a System register, as is the case with the AT * address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the PAR_EL1.
Note

This is consistent with the AArch32 requirement, where the VA to PA translation instructions are executed as writes to the (coproc==0b1111) System register encoding space, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.
D5.3 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats.
- ARMv8 translation table level 3 descriptor formats on page D5-2447.

Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449 then gives more information about the descriptor attribute fields, and Control of Secure or Non-secure memory access on page D5-2455 describes how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D5.3.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a Block descriptor is permitted.
- If a Block descriptor is permitted, the size of the memory region described by that entry.
- The maximum OA size, depending on whether ARMv8.2-LPA is implemented.

These differences depend on the translation granule, as follows:

4KB granule Level 0 translation tables do not support Block descriptors.

A block descriptor:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

The maximum OA size of a lookup is 48 bits.

16KB granule Level 0 and level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 32MB input address range.

The maximum OA size of a lookup is 48 bits.

64KB granule Level 0 lookup is not supported.

Other properties depend on whether ARMv8.2-LPA is implemented:

If ARMv8.2-LPA is implemented

A block descriptor:

- In a level 1 table describes the mapping of the associated 4TB input address range.
- In a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 48 bits.

If ARMv8.2-LPA is not implemented

Level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 48 bits.

When a lookup returns a Table descriptor, the OA is the next-level table address.
Figure D5-15 shows the ARMv8 level 0, level 1, and level 2 descriptor formats that provide 48-bit OAs:

### Block

<table>

</tbody>
</table>

A level 1 Table descriptor returns the address of the level 2 table.
A level 2 Table descriptor returns the address of the level 3 table.

† TA[51:48] indicates bits[51:48] of the next-level table address.

### Figure D5-16 VMSAv8-64 level 1 and level 2 descriptor formats, 64KB granule with ARMv8.2-LPA

--- Note ---
The effects on the Non-secure EL1 descriptors when ARMv8.1-HPD is enabled and HCR_EL2.{NV, NV1} == {1,1} are detailed in Effect of HCR_EL2.{NV, NV1} on page D5-2492.
Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Block  The descriptor gives the base address of a block of memory, and the attributes for that memory region.

1, Table  The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

64KB translation granule

For a level 1 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address and bits[47:42] are bits[47:42] of the output address. This output address specifies a 4TB block of memory.
- If ARMv8.2-LPA is not implemented, there is no level 1 Block descriptor.

For a level 2 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address, and bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.
- If ARMv8.2-LPA is not implemented, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

In ARMv8.0, bits[63:52, 11:2] provide attributes for the target memory block. When ARMv8.1-TTHM is implemented, bits[63:51, 11:2] provide the attributes for the target memory block. For more information, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449.

Note

- In ARMv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the Page descriptors.
- When ARMv8.2-TTPBHA is implemented, hardware can use bits[62:59] of the Block descriptors for IMPLEMENTATION DEFINED purposes, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449.
Table descriptor

Gives the translation table address for the next-level lookup, as follows:

4KB translation granule

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

16KB translation granule

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

64KB translation granule

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
  - When ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the required next-level table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449.

If the translation table defines the either the Secure or Non-secure EL1&0, when EL2 is enabled, stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

D5.3.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D5-17 on page D5-2448 shows the ARMv8 level 3 descriptor formats.
Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page

Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Gives the output address of a page of memory, as follows:

4KB translation granule

Bits[47:12] are bits[47:12] of the output address for a page of memory.

16KB translation granule

64KB translation granule

If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] and bits[47:16] are bits[47:16] of the output address for a page of memory. If ARMv8.2-LPA is not implemented, bits[47:16] are bits[47:16] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449.

--- Note ---

- In ARMv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.
- When ARMv8.1-TTHM is implemented, the position and contents of bits[63:51, 11:2] are identical to bits[63:51, 11:2] in the level 0, level 1, and level 2 block descriptors.
When ARMv8.2-TTPBHA is implemented, hardware can use bits[62:59] of the Page descriptors for IMPLEMENTATION DEFINED purposes, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors*.

For either the Secure or Non-secure EL1&0, when EL2 is enabled, stage 1 translations, the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

## D5.3.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors

*Memory region attributes on page D5-2476 describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:*

### Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see *Next-level attributes in stage 1 VMSAv8-64 Table descriptors*.

### Block and page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- *Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors* on page D5-2451
- *Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors* on page D5-2453.

### Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:51] are IGNORED:

Next-level descriptor attributes, stage 1 only

<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>61</th>
<th>60</th>
<th>59</th>
<th>58</th>
<th>51</th>
</tr>
</thead>
<tbody>
<tr>
<td>NSTable</td>
<td>APTable</td>
<td>UXNTable or XNTable</td>
<td>PXNTable</td>
<td>IGNORED</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

† UXNTable for a translation regime that can apply to execution at EL0, otherwise XNTable.
‡ RES0 for a translation regime that cannot apply to execution at EL0.

These attributes are:

**NSTable, bit[63]**

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses on page D5-2455*.

For memory accesses from Non-secure state, including all accesses in the EL2 or EL2&0 translation regime, this bit is RES0 and is ignored by the PE.

**APTable, bits[62:61]**

Access permissions limit for subsequent levels of lookup, see *Hierarchical control of data access permissions on page D5-2460*.

APTable[0] is RES0:

- In the EL2 translation regime.
In an implementation that includes ARMv8.1-VHE, when the value of HCR_EL2.E2H is 1 the translation regime for memory accesses from EL2 is the EL2&0 translation regime. APTable[0] can be valid (not RES0) in the EL2&0 translation regime.

Note

In the EL3 translation regime.

From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_ELx.HPD1 is 1:

• The value of the corresponding APTable field is IGNORED by hardware, allowing the field to be used by software.
• The behavior of the system is as if the value of the corresponding APTable field is 0.

Note

From ARMv8.3, if EL2 is enabled in the current Security state, in the EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[61] is treated as 0 regardless of the actual value, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

UXNTable or XNTable, bit[60]

XN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D5-2465.

The naming of this field depends on whether stage 1 of the translation regime can support two VA ranges:

Stage 1 can support two VA ranges

This field is UXNTable, and determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted.

Note

PXNTable is the equivalent control of execution at a higher Exception level.

Stage 1 supports only one VA range

This field is XNTable.

From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_ELx.HPD1 is 1:

• The value of the corresponding UXNTable field is IGNORED by hardware, allowing the field to be used by software.
• The behavior of the system is as if the value of the corresponding UXNTable field is 0.

Note

From ARMv8.3, if EL2 is enabled in the current Security state, in the EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[60] holds PXNTable, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D5-2465.

This field is valid only for a stage 1 translation that can support two VA ranges. It is RES0 for stage 1 translations that can support only one VA range.

From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_ELx.HPD1 is 1:

• The value of the corresponding PXNTable field is IGNORED by hardware, allowing the field to be used by software.
• The behavior of the system is as if the value of the corresponding PXNTable field is 0.
D5.3 VMSA-64 translation table format descriptors

Note

From ARMv8.3, if EL2 is enabled in the current Security state, in the EL1&0 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[59] is RES0, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-7463. For more information about these fields see Other fields in the VMSA-64 translation table format descriptors on page D5-2480.

Attribute fields in stage 1 VMSA-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

† IGNORED if ARMv8.2-TTPBHA is not implemented.
‡ RES0 for a translation regime that cannot apply to execution at EL0.
UXN or XN† for a translation regime that can apply to execution at EL0, otherwise XN.
* RES0 if ARMv8.1-TTHM is not implemented.
§ RES0 if ARMv8.2-LPA is not implemented.

For a stage 1 descriptor, the attributes are:

PBHA, bits[62:59]

Page-based hardware attributes bits.

These bits are IGNORED when ARMv8.2-TTPBHA is not implemented.

When ARMv8.2-TTPBHA is implemented, each TCR_ELx has a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit, TCR_ELx.HPD{n} is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes.

The TCR_ELx control bits for this feature are:

For a translation regime that supports only a single VA range

HWU0nn Controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD0 is 1.

For a translation regime that can support two VA ranges

HWU0nn For the translation tables indicated by TTBR0_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD0 is 1.

HWU1nn For the translation tables indicated by TTBR1_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD1 is 1.

If ARMv8.2-TTPBHA is not implemented, then the TCR_ELx control bits are RAZ/WI.
XN or UXN, bit[54]
The Execute-never or Unprivileged execute-never field, see Access permissions for instruction execution on page D5-2461.

Note
From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[54] holds PXN, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

PXN, bit[53]
The Privileged execute-never field, see Access permissions for instruction execution on page D5-2461.

This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.

Note
From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[53] is RES0, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

Contiguous, bit[52]
A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see The Contiguous bit on page D5-2481.

DBM, bit[51]
Dirty Bit Modifier, see The dirty state on page D5-2466.

nT, bit[16]
Block translation entry, see Block translation entry on page D5-2467.

If ARMv8.4-TTRem is implemented, this field is present in stage 1 block translation table entries. Otherwise, this field is RES0.

The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See Global and process-specific translation table entries on page D5-2512.

This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.

AF, bit[10]
The Access flag, see The Access flag on page D5-2466.

SH, bits[9:8]
Shareability field, see Memory region attributes on page D5-2476.

AP[2:1], bits[7:6]
Data Access Permissions bits, see Memory access control on page D5-2456.

Note
The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is valid only for stage 1 of a translation regime that can support two VA ranges. It is RES1 when stage 1 translations can support only one VA range.

Note
From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[6] is treated as 0 regardless of its actual value, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.

NS, bit[5]
Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access on page D5-2455.
For memory accesses from Non-secure state this bit is RES0 and is ignored by the PE.

**AttrIndx[2:0], bits[4:2]**

Stage 1 memory attributes index field, for the MAIR_ELx, see *Stage 1 memory region type and Cacheability attributes on page D5-2476.*

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see *IGNORED on page Glossary-7463.* For more information about these fields see *Other fields in the VMSAv8-64 translation table format descriptors on page D5-2480.*

**Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors**

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

![Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors when ARMv8.4-S2FWB is implemented](image)

For a stage 2 descriptor, the attributes are:

**PBHA, bits[62:59]**

Page-based hardware attributes bits.

These bits are IGNORED and reserved for System MMU use when ARMv8.2-TTPBHA is not implemented.

When ARMv8.2-TTPBHA is implemented, VTCR_EL2 has a control bit for each PBHA bit in the EL1&0 stage 2 translation tables. When the value of that control bit is 1, hardware can use the corresponding PBHA bit for IMPLEMENTATION DEFINED purposes.

If ARMv8.2-TTPBHA is not implemented, then the VTCR_EL2 control bits are RAZ/WI.

**XN[1:0], bits[54:53]**

The Execute-never field, see *Access permissions for instruction execution on page D5-2461.*

If ARMv8.2-TTS2UXN is not implemented, bit[53] is RES0.

**Contiguous, bit[52]**

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit on page D5-2481.*

**DBM, bit[51]**

Dirty Bit Modifier, see *The dirty state on page D5-2466.*

**nT, bit[16]**

Block translation entry, see *Block translation entry on page D5-2467.*

If ARMv8.4-TTRem is implemented, this field is present in stage 2 block translation table entries. Otherwise, this field is RES0.
**AF, bit[10]**  
The Access flag, see *The Access flag on page D5-2466.*

**SH, bits[9:8]**  
Shareability field, see *The stage 2 memory region attributes, EL1&0 translation regime on page D5-2478.*

**S2AP, bits[7:6]**  
Stage 2 data Access Permissions bits, see *The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2460.*

--- Note ---
In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

**MemAttr, bits[5:2]**  
Stage 2 memory attributes, see *The stage 2 memory region attributes, EL1&0 translation regime on page D5-2478.*

The definition of **IGNORED** means the architecture guarantees that the PE makes no use of the field, see *IGNORED on page Glossary-7463.* For more information about these fields see *Other fields in the VMSAv8-64 translation table format descriptors on page D5-2480.*
D5.3.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether
  the access is to Secure or Non-secure memory.
- Is ignored by:
  - Accesses from Non-secure state.
  - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see Hierarchical
  control of Secure or Non-secure memory accesses.

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table
descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit
in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

- **NS == 0**  Access the Secure PA space.
- **NS == 1**  Access the Non-secure PA space.

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the
 corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the
 value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates
whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state,
the meaning of the NSTable bit is:

- **NSTable == 0**  The defined table address is in the Secure PA space. In the descriptors in that translation table, NS
  bits and NSTable bits have their defined meanings.

- **NSTable == 1**  The defined table address is in the Non-secure PA space. Because this table is fetched from the
  Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored.
  This means that, for this table:
    - The value of the NS bit in any block or page descriptor is ignored. The block or page address
      refers to Non-secure memory.
    - The value of the NSTable bit in any table descriptor is ignored, and the table address refers
      to Non-secure memory. When this table is accessed, the NS bit in any block or page
      descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from the Non-secure IPA space
memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more
information about the nG bit, see Global and process-specific translation table entries on page D5-2512.

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or
more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that
the effect of the change is visible to subsequent memory transactions.
D5.4 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- About access permissions.
- About PSTATE.PAN on page D5-2457.
- About PSTATE.UAO on page D5-2458.
- Data access permission controls on page D5-2458.
- Access permissions for instruction execution on page D5-2461.
- The Access flag on page D5-2466.
- The dirty state on page D5-2466.
- Software management of the Access flag on page D5-2467.
- Hardware management of the Access flag and dirty state on page D5-2467.
- Ordering of hardware updates to the translation tables on page D5-2473.
- Restriction on memory types for hardware updates on translation tables on page D5-2474.
- Use of the Contiguous bit with hardware updates of the translation table entries on page D5-2475.

Note

This section describes the access controls for each of the translation regimes, and for each stage of translation in the EL1&0, when EL2 is enabled, translation regime.

A translation applies to memory accesses from either:

- Only a single Exception level, for example the EL3 translation regime.
- EL0 and one higher Exception level, for example the EL1&0 translation regime.

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. Control of Secure or Non-secure memory access on page D5-2455 describes the address map control, and Memory region attributes on page D5-2476 describes the other fields.

D5.4.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writable locations, see Preventing execution from writable locations on page D5-2466.
- For the effect of disabling a stage of address translation on the access permissions see The effects of disabling a stage of address translation on page D5-2437.
- From ARMv8.1, the PSTATE.PAN bit can affect the access permissions for privileged data accesses, see About PSTATE.PAN on page D5-2457.
- From ARMv8.2, the PSTATE.UAO bit can affect the access permissions for unprivileged instructions, see About PSTATE.UAO on page D5-2458.

Note

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 can see only the access permissions defined by the EL1&0, when EL2 is enabled, stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the software executing at EL1 or EL0.
The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see *The AP[2:1] data access permissions, for stage 1 translations* on page D5-2458.

  — **Note** —

  The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see *The VMSAv8-32 Short-descriptor translation table format* on page G5-5473. The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see *The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime* on page D5-2460.

- Uses the UXN, XN and PXN fields to define access controls for instruction fetches, see *Access permissions for instruction execution* on page D5-2461.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

—— **Note** ———

In an implementation that includes EL2, each stage of the translation of a memory access made using the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime has its own, independent, permission check.

### D5.4.2 About PSTATE.PAN

When the value of PSTATE.PAN is 1, any privileged data access from EL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in ARMv8.0.

When ARMv8.1-PAN is implemented, the SPSR_EL1.PAN, SPSR_EL2.PAN, and SPSR_EL3.PAN bits are used for exception returns, and the DSPSR_EL0 register is used for entry to or exit from Debug state.

When ARMv8.1-PAN is implemented, the SCTLR_EL1.SPAN and SCTLR_EL2.SPAN bits are used to control whether the PAN bit is set on an exception to EL1 or EL2.

When HCR_EL2.{E2H, TGE} == {1, 1} SCTLR_EL1.SPAN and SCTLR_EL2.SPAN are ignored.

The PAN bit has no effect on:

- Data Cache instructions other than DC ZVA.
- Address translation instructions, other than ATS1E1RP and ATS1E1WP when ARMv8.2-ATS1E1 is implemented.
- Unprivileged instructions, LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, STTR, STTRB, and STTRH, unless HCR_EL2.{E2H, TGE} == {1, 0}.
- Instruction accesses.

If access is disabled, then the access will give rise to a stage 1 Permission fault.

On an exception that is taken from AArch64 to AArch64, PSTATE.PAN is copied to SPSR_ELx.PAN.

On an exception return from AArch64:

- **SPSR_ELx.PAN** is copied to PSTATE.PAN, when the target Exception level is in AArch64.
- **SPSR_ELx.PAN** is copied to CPSR.PAN, when the target Exception level is in AArch32.

—— **Note** ———

- In Non-debug state, in AArch64 state:
  — Software can use an MSR PAN, #Imm4 or MSR PAN, Xr instruction to modify PSTATE.PAN, or an MRS Xr, PAN instruction to read PSTATE.PAN.
— In EL1, when HCR_EL2.{NV, NV1} == {1, 1}, PSTATE.PAN is treated as 0 for all purposes except reading the value of the bit.

• In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify PSTATE.PAN.

D5.4.3 About PSTATE.UAO

When the value of PSTATE.UAO is 1, a Load/Store unprivileged instruction executed at EL1, or executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} is subject to the memory access permissions that apply to the Exception level at which it is executed, rather than being subject to the EL0 access permissions. This means the Load/Store unprivileged instruction is subject to the same access permissions as the corresponding Load/Store register instruction. See Load/Store unprivileged on page C3-181 and Load/Store register on page C3-177.

When ARMv8.2-UAO is implemented and PSTATE.UAO is 0, it has no effect on the described behavior of any Load/Store unprivileged instruction.

A corresponding UAO bit is added to SPSR_EL1, SPSR_EL2, and SPSR_EL3 for exception returns, and DSPSR_EL0 for entry to or exit from Debug state.

On an exception that is taken from AArch64 state to AArch64 state, PSTATE.UAO is copied to SPSR_ELx.UAO and then set to 0.

On an exception that is taken from AArch32 state to AArch64 state:
• PSTATE.UAO is set to 0.
• SPSR_ELx.UAO is set to 0.

On an exception return from AArch64 state to AArch64 state, SPSR_ELx.UAO is copied to PSTATE.UAO.

___Note___

• In Non-debug state, in AArch64 state, software can use an MSR UAO, #Imm4 or MSR UAO, Xt instruction to modify PSTATE.PAN, or an MRS Xt, UAO instruction to read PSTATE.UAO.

• In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify PSTATE.UAO.

D5.4.4 Data access permission controls

The following subsubsections describe the data access permission controls:

• The AP[2:1] data access permissions, for stage 1 translations.
• The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2460.
• Hierarchical control of data access permissions on page D5-2460.

The AP[2:1] data access permissions, for stage 1 translations

In VMSAv8-64, for a translation regime that applies to both EL0 and a higher Exception level, the AP[2:1] bits control the stage 1 data access permissions, and:

AP[2] Selects between read-only and read/write access.
AP[1] Selects between Application level (EL0) control and the higher Exception level control.

This provides four permission settings for data accesses:
• Read-only at all levels.
• Read/write at all levels.
• Read-only at the higher Exception level, no access by software executing at EL0.
• Read/write at the higher Exception level, no access by software executing at EL0.
Note

In an implementation that does not include ARMv8.1-VHE, the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE, the EL2&0 translation regime applies to both Non-secure EL0 and EL2 when the value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

For translation regimes that apply only to accesses from a single Exception level, AP[2] determines the stage 1 data access permissions, and AP[1] is RES1, meaning it is ignored by hardware and is treated as if it is 1.

Table D5-25 shows the meaning of the AP[2:1] field for stage 1 of a translation regime that applies to both EL0 and a higher Exception level. In this table, an entry of None indicates that any access from that Exception level faults.

### Table D5-25 Data access permissions for stage 1 translations that applies to EL0 and a higher Exception level

<table>
<thead>
<tr>
<th>AP[2:1]</th>
<th>Access from higher Exception level</th>
<th>Access from EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Read/write</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read/write</td>
<td>Read/write</td>
</tr>
<tr>
<td>10</td>
<td>Read-only</td>
<td>None</td>
</tr>
<tr>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime:

- The stage 2 translation also defines data access permissions, see The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2460.
- When both stages of translation are enabled, Combining the stage 1 and stage 2 data access permissions on page D5-2483 describes how these permissions are combined.

Table D5-26 shows the effect of the AP[2] field for stage 1 of a translation regime that applies to only a single Exception level.

### Table D5-26 Data access permissions for stage 1 translations that apply to only a single Exception level

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write</td>
</tr>
<tr>
<td>1</td>
<td>Read-only</td>
</tr>
</tbody>
</table>
The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime

In the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D5-27 shows. In this table, an entry of None indicates that any access generates a Permission fault.

Table D5-27 Data access permissions for stage 2 of the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access from Non-secure EL1 or Non-secure EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read-only</td>
</tr>
<tr>
<td>10</td>
<td>Write-only</td>
</tr>
<tr>
<td>11</td>
<td>Read/write</td>
</tr>
</tbody>
</table>

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see Combining the stage 1 and stage 2 data access permissions on page D5-2483.

Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2482 gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

Note

Similar hierarchical controls apply to instruction fetching, see Hierarchical control of instruction fetching on page D5-2465.

However, in an implementation that includes ARMv8.1-HPD, when the value of a TCR_ELx.HPD{0} field is 1, or the value of the TCR_ELx.HPD1 field is 1, the hierarchical control of data access permissions is disabled for the translation stage controlled by that TCR_ELx, and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D5-28 shows. As stated in the table footnote, for a translation regime that applies to only a single Exception level, APTable[0] is RES0, meaning it is ignored by the hardware.

Table D5-28 Effect of APTable[1:0] on subsequent levels of lookup

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01*</td>
<td>Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>11*</td>
<td>Regardless of permissions in subsequent levels of lookup:</td>
</tr>
<tr>
<td></td>
<td>• Write access not permitted, at any Exception level.</td>
</tr>
<tr>
<td></td>
<td>• Read access not permitted at EL0.</td>
</tr>
</tbody>
</table>
The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**D5.4.5 Access permissions for instruction execution**

Execute-never controls determine whether instructions can be executed from a memory region. These controls are:

**UXN, Unprivileged execute-never, stage 1 only**
Descriptor bit[54], defined as UXN only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.
This field applies only to execution at EL0. A value of 0 indicates that this control permits execution.

**XN, Execute-never**
Descriptor bit[54], defined as XN for:
- Stage 1 of any translation regime for which the stage 1 translation can support only a single VA range.
- Stage 2 translations when ARMv8.2-TTS2UXN is not implemented.

**Note**

XN[1:0], Execute-never, stage 2 only describes the stage 2 control when ARMv8.2-TTS2UXN is implemented.

This field applies to execution at any Exception level to which the stage of translation applies. A value of 0 indicates that this control permits execution.

**PXN, Privileged execute-never, stage 1 only**
Descriptor bit[53], used only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.
- For stage 1 of a translation regime for which the stage 1 translation supports only a single VA range the stage 1 descriptors define a PXN field that is RES0, meaning it is ignored by hardware.
This field applies only to execution at an Exception level higher than EL0. A value of 0 indicates that this control permits execution.

**XN[1:0], Execute-never, stage 2 only**
Descriptor bits[54:53], defined as XN[1:0] for:
- Stage 2 translations when ARMv8.2-TTS2UXN is implemented.
Table D5-29 shows the operation of this control.

**Table D5-29 XN[1:0] stage 2 access permissions model**

</tr>
</tbody>
</table>

---

**Note**

For stage 2 translations when ARMv8.2-TTS2UXN is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware.

---

**Note**

In an implementation that does not include ARMv8.1-VHE, the only translation regime for which stage 1 translation can support two VA ranges is the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE:

- When the value of HCR_EL2.E2H is 1, TCR_EL2 controls the EL2&0 translation regime, and this regime:
  - Supports two VA ranges, corresponding to TTBR0_EL2 and TTBR1_EL2.
  - Always supports both UXN and PXN fields.
- Memory accesses from EL0 are translated using the EL2&0 translation regime only when the value of HCR_EL2.{E2H, TGE} is {1, 1}.

Table D5-29 shows the operation of the stage 2 XN[1:0] control, and for each single-bit execute-never field a value of 1 indicates that, at an exception level to which the control applies, instructions cannot be executed from the target memory region. In addition:

- For a translation regime that applies to EL0 and a higher Exception level, if the value of the AP[2:1] bits is 00b1, permitting write access from EL0, then the PXN field is treated as if it has the value 1, regardless of its actual value.
- In a translation regime with two stages of translation, a region is execute-never if execution is not permitted by the value of the applicable execute-never field in one or both of:
  - The stage 1 translation table descriptor.
  - The stage 2 translation table descriptor.
- For each translation regime, if the value of the corresponding SCTLR_ELx.WXN field is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN field. For more information, see Preventing execution from writable locations on page D5-2466.
- The SCR_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see Restriction on Secure instruction fetch on page D5-2466.

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

---

**Note**

Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
• The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.

• When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. Behavior of instruction fetches when all associated stages of translation are disabled on page D5-2438 describes how disabling all stages of address translation affects instruction fetching.

The following subsubsections give more information about the data access permission controls:

• Stage 1 instruction access and execution permissions.
• Stage 2 instruction execution permissions on page D5-2465.
• Hierarchical control of instruction fetching on page D5-2465.
• Preventing execution from writable locations on page D5-2466.
• Restriction on Secure instruction fetch on page D5-2466.

Stage 1 instruction access and execution permissions

Table D5-30 and Table D5-31 on page D5-2464 include the AP[2:1] read and write permissions shown in Table D5-25 on page D5-2459 and Table D5-26 on page D5-2459. These permissions are shown as:

R Indicates Read permission granted.
W Indicates Write permission granted.

Table D5-30 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to EL0 and a higher Exception level.

<sup>a</sup> Where ELx is the higher Exception level to which the translation regime applies.
<sup>b</sup> Not executable because of the SCTLR_ELx.WXN control, because region is writable at ELx.

---

**Note**

The Access permissions for an AArch64 translation regime that applies to only a single Exception level are consistent with the following fields in the translation table entries being treated as shown:

- AP treated as RES1.
- APTable[0] treated as RES0.
- PXN treated as RES0.
- PXNTable treated as RES0.
Stage 2 instruction execution permissions

For the Secure or Non-secure EL1&0, when EL2 is enabled, stage 2 translation, the XN fields in the stage 2 translation table descriptors control the execution permission, and this control is completely independent of the S2AP access permissions:

- When ARMv8.2-TTS2UXN is not implemented the stage 2 XN field is a 1-bit field that applies to execution at both EL0 and EL1, see XN, Execute-never on page D5-2461.
- When ARMv8.2-TTS2UXN is implemented the stage 2 XN field is a 2-bit field that provides independent control of execution from EL0 and execution from EL1, see XN[1:0], Execute-never, stage 2 only on page D5-2461.

See also Combining the stage 1 and stage 2 instruction execution permissions on page D5-2483.

Hierarchical control of instruction fetching

The VMSA8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

--- Note ---

Similar hierarchical controls apply to data accesses, see Hierarchical control of data access permissions on page D5-2460.

---

However, in an implementation that includes ARMv8.1-HPD, when the value of a TCR_ELx.HPD{0} field is 1, or the value of the TCR_ELx.HPD1 field is 1, the hierarchical control of instruction fetching is disabled for the translation stage controlled by that TCR_ELx, and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- UXNTable or XNTable restricts the execute-never control:
  - When the value of the XNTable bit is 1, the UXN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of the UXNTable bit is 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of a UXNTable or XNTable bit is 0 the bit has no effect.
- For a translation regime that applies to EL0 and a higher Exception level, PXNTable restricts the PXN control:
  - When the value of PXNTable is 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When the value of PXNTable is 0 it has no effect.

--- Note ---

The UXNTable, XNTable, and PXNTable settings are combined with the XN, UXN, and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

---

The UXNTable, XNTable, and PXNTable controls are provided only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of UXNTable, XNTable, or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to UXNTable, XNTable, or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
Preventing execution from writable locations

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as XN, PXN, or UXN, regardless of the value of the XN, PXN, or UXN bit:

- For a translation regime that applies to EL0 and a higher Exception value, when the value of the applicable SCTLR_ELx.WXN field is 1:
  - All regions that are writable from EL0 at stage 1 of the address translation are treated as XN.
  - All regions that are writable from EL1 at stage 1 of the address translation are treated as PXN.

- For a translation regime that applies to only a single Exception level, when the value of the applicable SCTLR_ELx.WXN field is 1, all regions that are writable at stage 1 of the address translation are treated as UXN.

**Note**

- The SCTLR_ELx.WXN controls are intended to be used in systems with very high security requirements.
- Setting a WXN field to 1 changes the interpretation of the translation table entry, overriding a zero value of a XN, UXN, or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN to remain static in normal operation. In particular, it is implementation defined whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. This means that any change of these fields without a corresponding change of VMID might require synchronization and TLB invalidation, as described in TLB maintenance requirements and the TLB maintenance instructions on page D5-2515.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR_EL3.SIF. When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1&0, when EL2 is disabled, translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in TLB maintenance requirements and the TLB maintenance instructions on page D5-2515.

In an implementation that does not implement EL3, the Effective value of this bit is 0.

D5.4.6 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

In ARMv8.0, the Access flag is managed by software as described in Software management of the Access flag on page D5-2467.

From ARMv8.1, the Access flag can be managed by hardware as described in Hardware management of the Access flag on page D5-2468.

**Note**

The support for hardware management of the Access flag applies only to the VMSAv8-64 translation regimes.

D5.4.7 The dirty state

The dirty state indicates whether a page or section of memory is modified.

The dirty state can be managed by hardware as described in Hardware management of dirty state on page D5-2469.

Where the dirty state is managed in hardware, the dirty state information is encoded using the access permission bits AP[2] and S2AP[1] in conjunction with the DBM bit.
D5.4.8 Block translation entry

While the nT bit is set, if the implementation meets either level 1 or level 2 support, the PE either:

- Generates a translation fault when using a translation table entry that has the nT bit set. Such an entry is not permitted to be cached within the TLB.
- Guarantees that using a translation table entry that has the nT bit set does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors when an entry that does not have the nT bit set is translating the same address cached within the TLB.

--- Note ---

Using a translation table entry that has the nT bit set might significantly impact the performance of the translation.

For more information, see Support levels for changing block size on page D5-2517.

D5.4.9 Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

--- Note ---

If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

D5.4.10 Hardware management of the Access flag and dirty state

ARMv8.1 introduces the following optional features that perform hardware updates to the translation tables:

- Hardware management of the Access flag on page D5-2468.
- Hardware management of dirty state on page D5-2469.

The support for hardware management of the Access flag and dirty state is identified by the feature ARMv8.1-TTHM.

When the hardware management of the Access flag is enabled, in situations where, without this feature, an Access flag fault would be generated, the hardware instead performs an atomic read-modify-write of the appropriate translation table descriptor to update the Access flag from 0 to 1.

When the hardware management of dirty state is enabled, if the Block or Page descriptor in a translation table indicates that a data access does not have write permission, then in situations where, without this feature, a data access would generate a Permission fault only because of this lack of write permission, the hardware checks the value of the DBM field in the Block or Page descriptor. If this field is 1, then instead of generating a Permission fault, the hardware performs an atomic read-modify-write of the translation table descriptor, to change the value of the bit that prohibits the write access.

It is permissible, but not required, that a stage 2 permission failure on the stage 1 translation table walk has priority over the stage 1 abort generated by the stage 1 translation table entry if all the following are true:

- Stage 1 hardware updating of either access or dirty information is enabled.
• A stage 1 translation table entry results in the stage 1 translation table entry having the access or dirty bit updated.

• The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.

• The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a permission fault).

Hardware management of the Access flag

Hardware management of the Access flag is enabled, for the corresponding stage of address translation, by the following configuration fields:

For stage 1 translations

• TCR_EL1.HA.
• TCR_EL2.HA.
• TCR_EL3.HA.

For stage 2 translations

VTCR_EL2.HA.

Implementations are not required to support the hardware management of the Access flag. If ARMv8.1-TTHM is not supported, then the HA bit in TCR_EL1, TCR_EL2, TCR_EL3, and VTCR_EL2 is RES0.

When the value of a configuration bit, HA, is 1, then when a memory access is made using a translation table Block or Page descriptor from the corresponding stage of address translation:

• The PE sets the value of the Access flag to 1 in the translation table descriptor in memory, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  — The descriptor does not generate a Permission fault or an Alignment fault based on the memory type.
  — If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

When the PE updates the Access flag in this way no Access flag fault is generated.

• It is CONSTRAINED UNPREDICTABLE whether the PE sets the value of the Access flag in the translation table entry in memory to 1, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true.
  — The descriptor generates a Permission fault or an Alignment fault based on the memory type.
  — If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

This means that the value of the Access flag becomes UNKNOWN if the above conditions are all true.

The Access flag might be set to 1 as a result of speculative accesses by the PE.

—— Note ———

A consequence of the architectural rules for translation table accesses is that the architecture requires that for any translation to which an architecturally executed memory access occurs, the Access flag is set to 1, except as indicated in Using break-before-make when updating translation table entries on page D5-2516. However, because the architecture permits speculative accesses, the Access flag is permitted to be set to 1, even if there is no architecturally executed memory accesses by the processor.

When hardware updating of the Access flag is enabled, each stage of translation is treated independently. This means that a single memory access can cause a hardware update to either or both:

• The stage 1 Access flag.
• The stage 2 Access flag.
Since speculative accesses are permitted to update the Access flags, it is permissible for:

- The stage 1 Access flag for a translation of a virtual address to be updated in situations where the stage 2 translation of the associated intermediate physical address that is returned by the stage 1 of the virtual address does not permit access.
- The stage 2 Access flag for a translation of an intermediate physical address to be updated in situations where the stage 1 translation of the associated virtual address which returned that intermediate physical address does not permit access.

An address translation instruction for an address is permitted, but not required, to set the Access flag in the translation table entries for that address. Correspondingly, it is IMPLEMENTATION DEFINED whether such an instruction can generate a Data Abort if the Access flag for a stage of translation is updated to be set.

When hardware updates of the Access flag are enabled for a stage of translation an address translation instruction that uses that stage of translation will not report that the address will give rise to an Access flag fault in the PAR, and the result in PAR will be as if the value of the Access flag in the translation table entries for that address was 1.

**Hardware management of dirty state**

The hardware management of dirty state mechanism can only be enabled if hardware management of the Access flag is enabled. For information on the hardware management of the Access flag, see [Hardware management of the Access flag](#) on page D5-2468.

The hardware management of dirty state mechanism uses:

- In a stage 1 translation table access, the AP[2] bit in conjunction with the DBM bit in the translation table descriptors.
- In a stage 2 translation table access, the S2AP[1] bit in conjunction with the DBM bit in the translation table descriptors.

Hardware management of dirty state is enabled, for the corresponding stage of address translation, by the following configuration fields:

**For stage 1 translations**

- TCR_EL1.HD.
- TCR_EL2.HD.
- TCR_EL3.HD.

**For stage 2 translations**

VTCR_EL2.HD.

Implementations are not required to support the dirty state mechanism. If this mechanism is not supported, then the HD bit in TCR_EL1, TCR_EL2, TCR_EL3, and VTCR_EL2 is RES0.

When hardware management of dirty state is enabled, and a memory access is made using a translation table Block or Page descriptor:

- For a stage 1 address translation, if the value of the TCR_ELx.HD field corresponding to the address translation is 1, then the PE sets AP[2] to 0 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The value of the DBM field in the descriptor is 1.
  - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the AP[2] field is 1, indicating that the access does not have write permission.

When the PE updates AP[2] in this way no Permission fault is generated because of the value of the AP[2] field.
For a stage 2 address translation, if the value of the VTCR_EL2.HD field is 1, then the PE sets S2AP[1] to 1 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:

- The value of the DBM field in the descriptor is 1.
- If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the S2AP[1] field is 0, indicating that the access does not have write permission.

When the PE updates S2AP[1] in this way no Permission fault is generated because of the value of the S2AP[1] field.

**Note**
The PE that does the atomic update of the translation table descriptor is expected to ensure that any cached copy of that translation table descriptor for that PE is similarly updated, or removed from the TLB, so that multiple writes from the same thread on the same PE do not lead to multiple updates to the table. This is only a performance expectation.

If, for a write access, the PE finds that a cached copy of the descriptor in a TLB had the DBM bit set to 1 and the AP[2] or S2AP[1] bit set to the value that forbids writes, then the PE must check that the cached copy is not stale with regard to the descriptor entry in memory, and if necessary perform an atomic read-modify-write update of the descriptor in memory. This applies if the cached copy of the descriptor in a TLB is either:

- A stage 1 descriptor in which DBM has the value 1 and AP[2] has the value 1.
- A stage 2 descriptor in which DBM has the value 1 and S2AP[1] has the value 0.

**Note**
ARM expects that, in many implementations, any atomic update of a translation table entry required by the dirty state management mechanism will cause a translation table walk.

For the hardware updating of the AP[2] and S2AP[1] bits, each translation stage is treated independently. This means a single memory access can update either or both of:

- The stage 2 S2AP[1] bit.

The architecture does not permit updates to AP[2] and S2AP[1] by the hardware management of dirty state mechanism to occur as a result of speculative accesses by the PE that are not performed architecturally, except that for translation table entries for which the value of DBM is 1:

- A non-speculative access that passes its stage 1 permissions check can update AP[2] and subsequently encounter a stage 2 fault.

**Note**
This update of AP[2] is permitted even if the transaction subsequently encounters a stage 2 Translation fault or a Permission fault. This avoids a need to update both AP[2] and S2AP[1] as a single atomic update.

- A non-speculative access that generates an Alignment fault only because the memory type accessed is Device memory by a stage of translation can update AP[2] or S2AP[1] of that stage of translation if the memory access would have updated that translation table bit had the memory access not generated the Alignment fault.

- If the stage 2 hardware management of dirty state mechanism is enabled, the S2AP[1] field of a stage 2 translation table entry that is translating a stage 1 translation table without generating a stage 2 MMU fault:
  - Is updated from 0 to 1 as a result of a speculative update of the Access flag in an entry of that stage 1 translation table.
  - Is permitted to be updated speculatively from 0 to 1 as a result of performing a translation table walk using that stage 1 translation table, even if the entry in the stage 1 translation table is not updated. The speculative update is permitted to generate a synchronous External abort or an IMPLEMENTATION DEFINED abort caused by the memory type not supporting an atomic read-modify-write.
Note

This applies even if the stage 1 translation table contains entries that are not the final level entries and therefore would not be updated. This relaxation avoids the hardware complexity of having to detect whether the stage 1 entry is a final level entry before deciding to set the stage 2 dirty state information.

- If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then AP[2] and S2AP[1] bits associated with accesses from that instruction, which do not fault are permitted to be updated if the associated hardware update of dirty state mechanism is enabled.

For a Block or Page translation table descriptor for which the AF bit is 0, the DBM bit is 1, and either the value of the stage 1 AP[2] bit is 1 or the value of the stage 2 S2AP[1] bit is 0, both AF can be set to 1, and either AP[2] set to 0 or S2AP[1] set to 1, in a single atomic read-modify-write operation, as a result of an attempted write to a memory location that uses the translation table entry.

Implications of enabling the dirty state management mechanism

This subsection describes behaviors that result from having the dirty state management mechanism enabled for a particular stage of address translation.

For the final level of lookup in a stage 1 translation:

In the EL3 translation regime

The OA of the lookup is treated as writable if all of the following conditions apply:
- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup, the value of APTable[1] is 0.

In this case, if the value of SCTLR_EL3.WXN is 1 then the OA is treated as Execute-never.

In the EL2 or EL2&0 translation regime, when the value of HCR_EL2.{E2H, TGE} is not \{1, 1\}

Note

When the value of HCR_EL2.E2H is 1, TCR_EL2 controls the EL2&0 translation regime, and otherwise it controls the EL2 translation regime.

The OA of the lookup is treated as writable if all of the following conditions apply:
- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup the value of APTable[1] is 0.

In this the value of SCTLR_EL2.WXN is 1 then the OA is treated as Execute-never.

In addition, if the value of HCR_EL2.E2H is 1, the OA is treated as Privileged execute-never if all of the following conditions apply:
- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup, the value of APTable[1:0] is 0b00.

Note

When the value of HCR_EL2.{E2H, TGE} is not \{1, 1\}, memory accesses from EL0 do not use the EL2, or EL2&0, translation regime.
In the EL2&0 translation regime, when the value of HCR_EL2.{E2H, TGE} is \{1, 1\}

The OA of the lookup is treated as writable at EL2 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.

In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is also treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL2 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.

In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.

In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

In the EL1&0 translation regime

The OA of the lookup is treated as writable at EL1 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.

In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL1 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.

In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Privileged execute-never.

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  - In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b0x.

In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Privileged execute-never.

The OA of a translation table entry where the DBM bit is 1, and the stage 1 AP[2] bit is 1 or the stage 2 S2AP[1] bit is 0, is treated as writable:

- For data cache invalidation instructions that require write permission, that is for the DC IVAC instruction.
- For address translation instructions that require write permission, that is for the AT S1E0W, AT S1E1W, AT S1E0W, AT S1E1W, AT S1E2W, and AT S1E3W instructions.
Cache invalidation and address translation instructions never cause the stage 1 AP[2] bit or the stage 2 S2AP[1] bit in the translation table entry to be updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1 and the stage 1 AP[2] bit is 1, if the Store-Exclusive fails because the Exclusives monitor is not in the exclusive state, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the Store-Exclusive fails because the Exclusives monitor is not in the Exclusive access state, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated.

For a store to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated:
- If the memory location generates a synchronous External abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

For a store to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the Store-Exclusive fails because the Exclusives monitor is not in the Exclusive access state, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated:
- If the memory location generates a synchronous External abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

In the event of a PE setting the stage 1 AP[2] bit to 0, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

In the event of a PE setting the stage 2 S2AP[1] bit to 0, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

For the stage 2 translation tables, it is CONSTRAINED UNPREDICTABLE whether the stage 2 S2AP[1] entry is updated in response to a stage 1 translation table walk where the stage 1 translation system is configured to perform hardware updates to the Access flag or stage 1 AP[2] bit, but the values of the Access flag and AP[2] bit are such that a hardware update to the stage 1 translation table entry being accessed is not required.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and the stage 1 AP[2] bit is 1 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and stage 2 S2AP[1] bit is 0 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the AP[2] bit in the translation table is updated.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

For an atomic instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[0:1] is 00, if the instruction generates a stage 2 Permission fault as a result of not having read permission, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

### D5.4.11 Ordering of hardware updates to the translation tables

A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the shareability attributes:

- Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.
• Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table entry and the subsequent load.

• Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.

• Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction that caused the update to the translation table entry and the subsequent cache maintenance instruction.

An update to the translation table that is caused by a load is not ordered with respect to the load itself.

An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

D5.4.12 Restriction on memory types for hardware updates on translation tables

Translation tables can be placed in Normal memory with any cacheability, but the hardware updates to the translation tables require an atomic update of memory. The properties of the atomicity can be met only by functionality outside the PE. Some system implementations might not implement this functionality for all regions of memory. This can apply to:

• Any type of memory in the system that does not support hardware cache coherency.

• Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does not support hardware cache coherency.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the hardware updates of the translation tables will be atomic are:

• Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

• Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the hardware updates of the translation tables are not atomic in regard to other agents that access memory, then performing a hardware update to such a location can have one or more of the following effects:

• The hardware update generates a synchronous External abort, which is presented as an External abort on a translation table walk.

• The instruction generates a SError interrupt.

• The hardware update generates an Unsupported atomic hardware update MMU fault reported using the Fault status code of:
  — \( \text{ESR\_ELx.DFSC} = 110001 \) for Data Aborts.
  — \( \text{ESR\_ELx.IFSC} = 110001 \) for Instruction Aborts.

For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, if atomic hardware update is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.
The priority of this MMU fault for a stage of the translation is immediately before or immediately after the priority of a Permission fault generated by the same stage of translation as the stage of this MMU fault, as determined by an IMPLEMENTATION DEFINED choice.

- The hardware updates are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a SError interrupt.

D5.4.13 Use of the Contiguous bit with hardware updates of the translation table entries

Hardware updates of the Access flag, and the AP[2] or S2AP[1] bit, only apply to a single translation table entry. An update to one of these bits in a translation table entry that also has the Contiguous bit set to 1 can give rise to translation table entries that have different Access flag, or different AP[2] or S2AP[1] bits, within the members of a group of contiguous translation table entries.

This is acceptable under the architecture when using hardware updates of the translation table entries. In addition, an access or a write to a location translated by an entry that has the Contiguous bit set might not result in a hardware update of the Access flag or the AP[2] or S2AP[1] bit, if at least one entry in the set of contiguous translation table entries has the Access flag set to 1, or the AP[2] or S2AP[1] bit indicating that the entry is dirty.

Note

- The provision of the Contiguous bit permits, but does not require, the hardware to hold a single entry in a TLB for the set of translation table entries in the group, and to have updated only one or more of the Access flags and the AP[2] bit or S2AP[1] bit for the single translation table entry that gave rise to the TLB entry.

- A consequence of this is that software must combine the Access flag values, and AP[2] or S2AP[1] values, across all translation table entries in a contiguous group to determine whether any of the entries have been accessed or written to.

For more information on the Contiguous bit, see The Contiguous bit on page D5-2481.
D5.5 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, Combining the stage 1 and stage 2 attributes, EL1&0 translation regime on page D5-2482 describes how the assignments from the two stages are combined.

--- Note ---
In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

• Reduce the permitted cacheability of a region.
• Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

--- Note ---
• This section describes the memory region attributes for each of the translation regimes, and for each stage of translation in the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.

• A translation applies to memory accesses from either:
  — Only a single Exception level, for example the EL3 translation regime.
  — EL0 and one higher Exception level, for example the EL1&0 translation regime.

• In general, attribute assignment is simpler in a regime that applies to only a single Exception level, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:
  — AP[1] is RES1, meaning the PE ignores the value of the bit and behaves as if it is 1.
  — APTable[0] is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  — The PXN field is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  — The PXNTable bit is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.

D5.5.1 The stage 1 memory region attributes

The description of the memory region attributes in a translation descriptor divides into:

Memory type and Cacheability

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as remapping the memory type and attribute description. Stage 1 memory region type and Cacheability attributes describes this encoding.

Shareability

The SH[1:0] field in the translation table descriptor encodes shareability information. Stage 1 Shareability attribute, for Normal memory on page D5-2477 describes this encoding.

Stage 1 memory region type and Cacheability attributes

In the VMSAv8-64 translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the MAIR_ELx that specifies the attributes for the corresponding memory region. The required field is Attrn, where $n = \text{AttrIndx}[2:0]$. For more information about AttrIndx[2:0] see Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D5-2451.
Each MAIR_ELx is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the MAIR_ELx register descriptions for more information.

Each MAIR_ELx.Attrn field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or No Allocate, and the Transient allocation hints, if supported.

For more information about the memory type and attributes, see Memory types and attributes on page B2-122 and Cacheability, cache allocation hints, and cache transient hints on page D4-2356.

### Stage 1 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D5-32 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLEa</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

a. See Reserved values in System and memory-mapped registers and translation table entries on page K1-7231 for the permitted CONSTRAINED UNPREDICTABLE behavior.

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes

See Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D5-2485 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.
The stage 2 memory region attributes, EL1&0 translation regime

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- **Stage 2 memory region type and Cacheability attributes** describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. **Stage 2 Shareability attribute, for Normal memory on page D5-2479** describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- **Combining the stage 1 and stage 2 memory type attributes on page D5-2484.**
- **Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D5-2484.**
- **Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D5-2485.**

### Stage 2 memory region type and Cacheability attributes

Table D5-33 shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the Outer cacheability of a Normal memory region.

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Outer cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device. MemAttr[1:0] encodes the Device memory type.</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal. MemAttr[1:0] encodes the Inner Cacheability.</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Write-Through Cacheable</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Outer Write-Back Cacheable</td>
<td></td>
</tr>
</tbody>
</table>

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating Device memory, Table D5-34 shows the encoding of MemAttr[1:0].

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>

- When MemAttr[3:2] != 0b00, indicating Normal memory, Table D5-35 shows the encoding of MemAttr[1:0].

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE³</td>
</tr>
</tbody>
</table>
Note
• The stage 2 translation does not assign any allocation hints.
• The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  — MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

D5.5.4 Stage 2 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D5-36 shows the encoding of this field.

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

Table D5-36 MemAttr[1:0] encoding for Normal memory (continued)

Note
• This encoding is the same as the shareability encoding described in Stage 1 Shareability attribute, for Normal memory on page D5-2477.
• The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D5-2485 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

D5.5.5 Stage 2 memory region type and Cacheability attributes when ARMv8.4-S2FWB is implemented

When ARMv8.4-S2FWB is implemented and HCR_EL2.FWB is set to 1, then the MemAttr[5:0] is divided as follows:
• Bit[5] is RES0.

When bit[4] is one the effects of bits [3:2] are defined in Table D5-37.

Table D5-37 Effect of bit[4] == 1 on Cacheability and Memory Type

<table>
<thead>
<tr>
<th>Stage 1 Memory Type and Inner or Outer Cacheability attribute</th>
<th>Stage 2 Block/Descriptor Bits[3:2]</th>

</tbody>
</table>

When HCR_EL2.FWB is set to 1 and Bit[4] is 0, then the stage 2 memory type is Device. Bits[3:2] of the Stage 2 page or block descriptor define the Device memory attributes. The Device Memory attributes are defined in Table D5-38.

Table D5-38 Device Memory Attributes when Bit[4] == 0

<table>
<thead>
<tr>
<th>Stage 2 page/block descriptor bits [3:2]</th>

D5.5.6 Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:

• *The Contiguous hit on page D5-2481.*
• *IGNORED fields on page D5-2482.*
• *Field reserved for software use on page D5-2482.*
The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a contiguous output address range. The required number of adjacent entries depends on the current translation granule size, as follows:

**4KB granule** 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

**16KB granule** This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

- **Level 2 lookup** The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

- **Level 3 lookup** The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

**64KB granule** 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the Contiguous bit. Possible errors in programming the translation table registers on page D5-2432 describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the Contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

Use of the Contiguous bit with hardware updates of the translation table entries on page D5-2475 describes the effect of hardware management of the Access flag and dirty state on the Contiguous bit.

**Note**

When ARMv8.2-LVA is implemented, the level 1 block size for the 64KB granule does not support the Contiguous bit, and that field is RES0.
IGNORED fields

In the VMSAv8-64 translation table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 and stage 2 Table descriptors, bits[58:51] and bits[11:2].
- In the stage 1 and stage 2 Block and Page descriptors, bit[63] and bits[58:55].
- In the stage 1 and stage 2 Block and Page descriptors in an implementation that does not include ARMv8.2-TTPBHA, bits[62:59].

Of these fields:

- In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see Field reserved for software use.
- In the stage 2 block and page descriptors:
  - Bit[63] is reserved for use by a System MMU.
  - In an implementation that does not include ARMv8.2-TTPBHA, bits[62:59] are reserved for use by a System MMU.

Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and translation table descriptors, bits[58:55], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

Note

This means there is no need to invalidate the TLB if these bits are changed.

D5.5.7 Combining the stage 1 and stage 2 attributes, EL1&0 translation regime

When EL2 is enabled, the Secure or Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1. Stage 1 MMU faults are taken to EL1.
- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
  - Affect the stage 1 access permissions settings.
  - Take no account of whether the accesses are at EL1 or EL0.
  - Permit software executing at EL2 to assign a write-only attribute to a memory region. Stage 2 MMU faults are taken to EL2.

Note

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

If ARMv8.4-S2FWB is implemented and HCR_EL2.FWB is set to 0, there is no effect on the combination of stage 1 and stage 2 memory attributes or cacheability attributes.
When HCR_EL2.FWB is set to 1:

- If the stage 1 page or block descriptor specifies a cacheable memory type, then the specified cacheable memory hint is applied to the final cache allocation hint if the final memory type is cacheable.
- If the stage 1 page or block descriptor does not specify a cacheable memory type, then the final cache allocation hint is Read Allocate, Write Allocate if the final memory type is cacheable.

The effects of HCR_EL2.FWB apply to both Secure and Non-secure stage 2 translation regime.

When ARMv8.4-S2FWB is implemented, the architecture requires that CLIDR_EL1.{LOUU, LOIUS} are zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

**Combining the stage 1 and stage 2 data access permissions**

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *The AP[2:1] data access permissions, for stage 1 translations on page D5-2458.*
- The stage 2 permissions described in *The S2AP data access permissions, Secure or Non-secure EL1&0, when EL2 is enabled, translation regime on page D5-2460.*

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

**Combining the stage 1 and stage 2 instruction execution permissions**

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *Stage 1 instruction access and execution permissions on page D5-2463.*
- The stage 2 permissions described in *Stage 2 instruction execution permissions on page D5-2465.*

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.
Combining the stage 1 and stage 2 memory type attributes

Table D5-39 shows the rules for combining the stage 1 and stage 2 memory type assignments.

### Table D5-39 Combining the stage 1 and stage 2 memory type assignments

<table>
<thead>
<tr>
<th>Rule</th>
<th>If either stage of translation assigns:</th>
<th>The resultant memory type is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device has precedence over Normal</td>
<td>Any Device memory type</td>
<td>A Device memory type</td>
</tr>
<tr>
<td>non-Gathering has precedence over Gathering</td>
<td>A Device-nGxx memory type</td>
<td>A Device-nGxx memory type</td>
</tr>
<tr>
<td>non-Reordering has precedence over Reordering</td>
<td>A Device-nGnRx memory type</td>
<td>A Device-nGnRx memory type</td>
</tr>
<tr>
<td>No Early write acknowledge has precedence over Early write acknowledge</td>
<td>The Device-nGnRnE memory type</td>
<td>The Device-nGnRnE memory type</td>
</tr>
</tbody>
</table>

Regardless of any shareability attribute obtained as described in *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D5-2485:

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see *Combining the stage 1 and stage 2 cacheability attributes for Normal memory*.

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs then:

- If the value of HCR_EL2.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR_EL2.PTW is 1, then the memory access generates a stage 2 Permission fault.

### Combining the stage 1 and stage 2 cacheability attributes for Normal memory

For a Normal memory region, Table D5-40 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

### Table D5-40 Combining the stage 1 and stage 2 cacheability assignments for Normal memory

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
</tr>
</tbody>
</table>
Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D5-2484, is any type of Device memory.

- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D5-2484, is Normal memory, and the resultant cacheability, described in Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D5-2484, is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, Table D5-41 shows how the stage 1 and stage 2 shareability assignments are combined.

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer Shareable</td>
<td>Any</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Non-shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>

<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>

a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.
D5.6 Virtualization Host Extensions

ARMv8.1 introduces the Virtualization Host Extensions that provide enhanced support for a Type 2 virtualization solution, where there is a Host OS, which is either more privileged than the hypervisor, or is a peer of the hypervisor.

The Virtualization Host Extensions only apply to an implementation that includes EL2 using AArch64.

D5.6.1 State added by the Virtualization Host Extensions

The following state is added as part of the ARMv8.1-VHE:

- A configuration bit, E2H, is added to HCR_EL2.
- New registers:
  - CONTEXTIDR_EL2, which has the same format and contents as CONTEXTIDR_EL1.
  - TTBR1_EL2, which has the same format and contents as TTBR1_EL1.
- An EL2 virtual timer which is accessed using the registers CNTHV_CTL_EL2, CNTHV_CVAL_EL2, and CNTHV_TVAL_EL2. The registers take the same format as CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 respectively. The virtual offset is treated as 0 for this timer.

D5.6.2 Behavior of HCR_EL2.E2H

When the value of HCR_EL2.E2H is 0:

- There are no changes to the ARMv8 functionality other than the new state described in State added by the Virtualization Host Extensions.

  Note
  This means the translation regime controlled by TCR_EL2 is called the EL2 translation regime.

- The contents of TTBR1_EL2 are ignored by hardware, other than reads by an MRS instruction and writes by an MSR instruction.
- The Context ID matching breakpoint is disabled at EL2, and uses the value of CONTEXTIDR_EL1 at EL0 and EL1.

When the value of HCR_EL2.E2H is 1, and EL2 is enabled for the current Security state:

- The translation regime controlled by TCR_EL2 is the EL2&0 translation regime, and the behaviors of this translation regime differ from those of the EL2 translation regime.
- The EL2&0 translation regime behaves in the same way as stage 1 of the EL1&0 translation regime, with an upper address range translated by tables pointed to by TTBR1_EL2. The existing TTBR0_EL2 translates the lower address range of the EL2&0 translation regime and is extended to have the same contents and format as the TTBR0_EL1.
- The translation tables used in the EL2&0 translation regime take the same format as the EL1&0 translation regime. EL2 accesses are treated as privileged in this format.
- Context ID matching can occur at EL2. When executing at EL2, a Context ID matching breakpoint uses CONTEXTIDR_EL2.
- VMID and VMID + Context ID matching breakpoints do not match at EL2.
- The virtual offset is treated as 0 when CNTVCT_EL0 is read from EL2.
- The Privileged Access Never mechanism applies to accesses from EL2 to a virtual address which has access permitted in the EL2&0 translation regime.
- The following registers are redefined:
  - CNTHCTL_EL2.
If $\text{HCR\_EL2.\{E2H, TGE\}} = \{1, 0\}$, then all accesses from EL1 and EL0 are not included in the EL2&0 translation regime.

If $\text{HCR\_EL2.\{E2H, TGE\}} = \{1, 1\}$:

- The EL2&0 translation regime is used when executing at EL0 as well as when executing at EL2, where EL0 accesses are treated as unprivileged.

**Note**

Accesses from EL1 are not possible under this configuration.

- In EL2, the unprivileged instructions `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `STTR`, `STTRB` and `STTRH` act as if they are executing at EL0 for permission and watchpoint checking.
- Except for the purpose of reading the value held in the register, some fields in `HCR\_EL2` and all fields in `HSTR\_EL2` are treated as having a specific value.
- `SCTLR\_EL2` is redefined to include additional fields from `SCTLR\_EL1`, and to apply to execution at EL0.
- The following timer registers, and their equivalent AArch32 registers, are redefined to access the associated _EL2 register, rather than accessing the _EL0 register when in EL0:
  - `CNTP\_CTL\_EL0`.
  - `CNTP\_CV\_EL0`.
  - `CNTP\_TV\_EL0`.
  - `CNTV\_CTL\_EL0`.
  - `CNTV\_CV\_EL0`.
  - `CNTV\_TV\_EL0`.

For some information on registers that are redirected, see *System and Special-purpose register redirection*.

- When executing at EL0, a Context ID matching breakpoint uses `CONTEXTIDR\_EL2`.
- `VMID` and `VMID + Context ID matching breakpoints do not match at EL0`.
- The `CPACR\_EL1` register does not cause any instructions to be trapped to EL1, regardless of the contents of `CPACR\_EL1`.
- The `CNTKCTL\_EL1` register does not cause any instructions to be trapped to EL1, and the event stream event caused by the `CNTKCTL\_EL1` is disabled, regardless of the contents of `CNTKCTL\_EL1`.
- The virtual offset is treated as 0 when `CNTVCT\_EL0` is read from EL0 or EL2.
- The TLB maintenance and address translation instructions that apply to the EL1&0 translation regime are redefined to apply to the EL2&0 translation regime. See *A64 System instructions for address translation* on page C5-452 and *A64 System instructions for TLB maintenance* on page C5-479.
- When executing at EL2 or EL0, any physical interrupt that is configured to be taken at EL2 is subject to the `PSTATE.\{D, A, I, F\}` interrupt masks. If the mask bit is set, then the corresponding interrupt will not be taken. If the mask bit is not set, then the corresponding interrupt will be taken. See *Asynchronous exception masking* on page D1-2202.
- When an exception is taken from EL0 to EL2, the value of the `HCR\_EL2.RW` bit is not considered when determining the exception vector offset to use. Table D1-7 on page D1-2172 lists the vector offsets used when an exception is taken from EL0.

### D5.6.3 System and Special-purpose register redirection

When ARMv8.1-VHE is implemented, and `HCR\_EL2.E2H` is set to 1, when executing at EL2, some EL1 System register access instructions are redefined to access the equivalent EL2 register.
Table D5-42 shows the System register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

<table>
<thead>
<tr>

D5.6.4 System and Special-purpose register aliasing

New register encodings, and aliases, are provided so that software executing at EL2 can access the EL1 registers for which accesses from EL2 are redirected as described in System and Special-purpose register redirection on page D5-2487. These aliases can also be used at EL3, but are UNDEFINED at EL1 and EL0.
Table D5-44 shows the System register access instruction encodings that are aliased.

D5.7 Nested virtualization

From ARMv8.3, nested virtualization is supported in AArch64 state:

- If ARMv8.3-NV is implemented, a Host hypervisor executing at EL2 can run a Guest hypervisor at EL1, see ARMv8.3 nested virtualization functionality.
- If ARMv8.4-NV is implemented, the PE further transforms System register accesses into memory accesses, see Enhanced support for nested virtualization on page D5-2494.

D5.7.1 ARMv8.3 nested virtualization functionality

Note

- When running a Guest hypervisor with HCR_EL2.E2H == 0, the Host hypervisor must set HCR_EL2.TVM and CPTR_EL2.TCPAC to trap any Guest hypervisor accesses to the EL1 System registers that would be accesses from any Guest OS running under the Guest hypervisor
- ARMv8.3-NV does not introduce any changes to either debug or to the Performance Monitors. ARM assumes that the Host hypervisor will trap accesses to the Breakpoint and Performance Monitors registers to EL2, so that it can process any accesses to these registers made by a Guest hypervisor or by a Guest OS running under the Guest hypervisor.

ARMv8.3-NV adds the fields HCR_EL2.{NV, NV1, AT}, see:

- Effect of HCR_EL2.{NV, NV1}.
- Effect of HCR_EL2.AT on page D5-2494.

Effect of HCR_EL2.{NV, NV1}

The following subsections describe the effect of HCR_EL2.{NV, NV1}:

- Behavior when HCR_EL2.NV == 1.
- Additional behavior when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 0 on page D5-2493.
- Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D5-2493.
- Behavior when HCR_EL2.NV == 0 and HCR_EL2.NV1 == 1 on page D5-2493.

HCR_EL2.{NV, NV1} are both permitted to be cached in a TLB.

Behavior when HCR_EL2.NV==1

The following behaviors apply when the value of HCR_EL2.NV is 1, regardless of the value of HCR_EL2.NV1. At EL1:

- Reads or writes to any allocated and implemented System register or Special-purpose register named *_EL2, _EL02, or *_EL12 in the MSR or MSR instruction, other than SP_EL2, are trapped to EL2 rather than being UNDEFINED. In this case, ESR_EL2 uses the EC code of 0x18. Only accesses that are permitted at EL2 are trapped. This means that, for example, if the register is a read-only register at EL2, then an MSR from Non-secure EL1 to the register is not trapped by this mechanism. Instead the register access remains UNDEFINED.

Note

The priority of this trapping relative to other configurable traps follows the standard hierarchy of exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.
• Reads or writes to `SP_EL1` using the dedicated `MRS` and `MSR` instruction for accessing that register are trapped to EL2 rather than being `UNDEFINED`. In this case the exception is reported in `ESR_EL2` using the EC code `0x18`.

• Execution of the EL2 translation regime Address translation instructions and TLB maintenance instructions are trapped to EL2 rather than being `UNDEFINED`. In this case the exception is reported in `ESR_EL2` using the EC code `0x18`.

• Execution of the EL1 translation regime Address translation instructions and TLB maintenance instructions that are only accessible from EL2 and above are trapped to EL2 rather than being `UNDEFINED`. In this case the exception is reported in `ESR_EL2` using the EC code `0x18`.

• The `ERETAA`, `ERETAB`, and `ERET` instructions are trapped to EL2. In this case the exception is reported in `ESR_EL2` using the EC code `0x1A`.

--- Note ---
The `ERETAA` and `ERETAB` instructions are only available when ARMv8.3-PAuth is implemented.

• A read of `CurrentEL` returns the value `0x2` in bits `[3:2].`

• If EL3 is not implemented and `HCR_EL2.TSC` == 1, an `SMC` instruction executed at EL1 is trapped to EL2 rather than being `UNDEFINED`, and `HCR_EL2.TSC` is not `RES0`. In this case the exception is reported in `ESR_EL2` using the EC code `0x17`.

**Additional behavior when `HCR_EL2.NV` == 1 and `HCR_EL2.NV1` == 0**

At EL1, all the behaviors described in `Behavior when HCR_EL2.NV==1` on page D5-2492 apply.

In addition, when `HCR_EL2.{NV, NV1} == {1, 0}`, any exception taken from EL1 to EL1 causes `SPSR_EL1.M[3:2]` to be set to `0b10` rather than `0b01`.

**Additional behaviors when `HCR_EL2.NV` == 1 and `HCR_EL2.NV1` == 1**

At Non-secure EL1, all the behaviors described in `Behavior when HCR_EL2.NV==1` on page D5-2492 apply.

In addition, when `HCR_EL2.{NV, NV1} == {1, 1}`:

• Accesses to `VBAR_EL1`, `ELR_EL1`, and `SPSR_EL1` from EL1 are trapped to EL2. In this case the exception is reported in `ESR_EL2` using the EC code `0x18`.

• In the EL1 translation table Block and Page descriptors:
  — Bit `[54]` holds PXN, not UXN.
  — Bit `[53]` is `RES0`.
  — Bit `[6]` is treated as 0 regardless of the actual value.

• If Hierarchical permissions are enabled, then in the EL1 translation table Table descriptor:
  — Bit `[61]` is treated as 0 regardless of the actual value.
  — Bit `[60]` holds PXNTable, not UXNTable.
  — Bit `[59]` is `RES0`.

• When in EL1, `PSTATE.PAN` is treated as 0 for all purposes except reading the value of the bit.

• When executed at EL1, the `LDTR*` behave as the corresponding `LDR*` instructions, and the `STTR*` instructions behave as the equivalent `STR*` instructions.

**Behavior when `HCR_EL2.NV` == 0 and `HCR_EL2.NV1` == 1**

When `HCR_EL2.{NV, NV1} == {0, 1}`, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

• Behaving as if `HCR_EL2.NV==1` and `HCR_EL2.NV1==1` for all purposes other than reading back the value of the `HCR_EL2.NV` bit.
Behaving as if $HCR_{EL2}.NV == 0$ and $HCR_{EL2}.NV1 == 0$ for all purposes other than reading back the value of the $HCR_{EL2}.NV1$ bit.

Behaving as defined for $HCR_{EL2}.NV == 0$, with $HCR_{EL2}.NV1 == 1$ having the effect of causing accesses to $VBAR_{EL1}$, $ELR_{EL1}$, and $SPSR_{EL1}$ from EL1 to be trapped to EL2.

**Effect of $HCR_{EL2}.AT$**

When ARMv8.3-NV is implemented, if $HCR_{EL2}.AT$ is 1, then EL1 accesses to AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, and AT S1E1WP, are trapped to EL2. In this case the exception is reported in ESR_EL2 using the EC code $0x18$.

**D5.7.2 Enhanced support for nested virtualization**

If ARMv8.4-NV is implemented, the PE can access the VNCR_EL2 register and the control bit $HCR_{EL2}.NV2$.

When $HCR_{EL2}.NV2$ is 1:

- When in EL1, the PE redirects EL2 register accesses to EL1 register accesses, see Redirection of register accesses from EL2 to EL1.
- When a Guest hypervisor issues System register access instructions to a Guest Guest OS, the PE transforms the System register access instructions into memory access instructions, see Loads and stores generated by transforming register accesses.

When $HCR_{EL2}.NV2$ is 0, the behavior of $HCR_{EL2}.NV$ and $HCR_{EL2}.NV1$ are as described in ARMv8.3 nested virtualization functionality on page D5-2492.

### Redirection of register accesses from EL2 to EL1

When $HCR_{EL2}.NV$ and $HCR_{EL2}.NV2$ are set to 1, instructions accessing certain Special-purpose EL2 registers executed at EL1 are redefined to access the corresponding EL1 register:

**Table D5-46 Redirection of accesses to special-purpose registers at EL2**

<table>
<thead>
<tr>
<th>Special register access instruction a</th>
<th>Named EL2 register</th>
<th>Actual register accessed</th>
</tr>
</thead>
<tbody>
<tr>

<td>ELR_EL2</td>
<td>ELR_EL1</td>
</tr>
</tbody>
</table>

a. For further information see op0==0b11, Moves to and from Special-purpose registers on page C5-348.

When $HCR_{EL2}.NV$ and $HCR_{EL2}.NV2$ are set to 1, instructions accessing certain System registers executed at EL1 are redefined to access the corresponding EL1 register:

**Table D5-47 Redirection of accesses to System registers at EL2**

<table>
<thead>
<tr>
<th>System register access instruction a</th>

</tr>
</tbody>
</table>

a. For further information see Instructions for accessing non-debug System registers on page D11-2659.

### Loads and stores generated by transforming register accesses

When an MRS or MSR instruction is executed at EL1 and is accessing a register listed in Table D5-48 on page D5-2495, the PE transforms that access into a loads or store, respectively.
When the PE transforms a System register access into a memory accesses, the address of the resulting memory access is defined using a combination of a base address and an offset according to the formula
\[
\text{SignExtend}(\text{VNCR.BADDR} : \text{Offset}<11:0>, 64):
\]

- \(\text{VNCR_EL2}\) holds the base memory address used for memory redirection of System register accesses.
- Each register which supports redirection to memory has a unique offset value, see Table D5-48.

**Table D5-48 Memory address offsets associated with each transformed register access**

**Note**

Software should assume that future expansion of the architecture will allocate offset values up to but not including 0x1000.

Registers that affect hypervisor execution by controlling the event stream are not included in Table D5-48 on page D5-2495:

- **CNTHCTL_EL2**
- When HCR_EL2.NV1 is 0, CNTHCTL_EL2.
- When HCR_EL2.NV1 is 1, CNTHCTL_EL2.
When a System register access is transformed into a memory access, that memory access has a defined format:

- The address of the memory access is translated by the EL2 translation regime.
- The endianness of the memory access is defined by SCTLR_EL2.EE.
- The memory access is 64-bit single-copy atomic aligned to 64 bits.
- The memory access does not have acquire or release semantics.

--- Note ---

The value of the transformed System register access is not affected by fields that are defined to be RES0 or RES1 in the associated System register.

---

- When there is no context synchronizing operation between the read or write of the register and the load or store instruction accessing the address, the PE is permitted, but not required, to reorder the memory accesses with respect to any EL1 reads or writes generated by load or store instructions to the same address.
- The memory accesses behave as if PSTATE.PAN == 0 regardless of the value of PSTATE.PAN.

When a register access instruction targets a register that is not implemented, the PE treats access to that register as UNALLOCATED.

Any attempt to trap a register access instruction is subject to the exception prioritization rules, unless it is trapped by either or both of HCR_EL2.{NV, NV1}. When a System register access instruction is trapped by either or both of HCR_EL2{NV, NV1}, then the instruction is transformed into a memory access instruction instead of creating a trap, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.

### Exceptions from transformed register accesses

When HCR_EL2.{NV2, NV} == {1,1} any exception taken from EL1 and taken to EL1 causes the SPSR_EL1.M[3:2] to be set to 0b10 and not 0b01.

When the memory access generates a Data Abort, then the resulting fault has a defined format:

- The fault is taken to EL2, using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current exception level with the ESR_EL2.EC code 0x25, see ISS encoding for an exception from a Data Abort on page D12-2792.
- FAR_EL2 is updated to hold the faulting address.

When the memory access generates a synchronous External abort, and when External aborts are not configured to be taken to EL3, then the resulting fault has a defined format:

- The fault is taken to EL2 using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current Exception level with ESR_EL2.EC code 0x25, see ISS encoding for an exception from a Data Abort on page D12-2792.

The VNCR field in ESR_EL2 and ESR_EL3 identifies whether the fault came from use of VNCR_EL2 by EL1, see ISS encoding for an exception from a Data Abort on page D12-2792.

### Interaction with self-hosted and External debug

When a register access is transformed into a memory access, the PE checks the memory access against the watchpoint registers as an EL2 access.

When the memory access matches an EL2 access in the watchpoint registers, while a watchpoint is linked to a context-aware breakpoint that is programmed to match the value held in CONTEXTIDR_EL1, then it is CONSTRAINED UNPREDICTABLE whether there is a watchpoint match.
A breakpoint programmed to match the value held in CONTEXTIDR_EL1 falls under one of four classes of breakpoint:

- 0b0011, Linked Context ID Match breakpoint.
- 0b0111, Linked CONTEXTIDR_EL1 Match.
- 0b1011, Linked Context ID and VMID Match breakpoint.
- 0b1111, Linked Full Context ID Match.

If ARMv8.4-NV is implemented, the hypervisor must use the 0b1101, Linked CONTEXTIDR_EL2 Match breakpoint type to guarantee a linked match.

When there is a watchpoint match, while EDSCR.HDE is set to 1 and halting is allowed, the watchpoint match generates a Watchpoint debug event.

When there is a watchpoint match, while EDSCR.HDE is set to 0 and debug exceptions are enabled at EL2, then the watchpoint match generates a Watchpoint exception.

When the watchpoint match generates a Watchpoint exception, the resulting exception has a defined format:

- The exception is taken to EL2.
- The exception is reported as a Watchpoint from the current Exception level with the ESR_EL2.EC code 0x35, see ISS encoding for an exception from a Watchpoint exception on page D12-2801.
- FAR_EL2 is updated to hold the watchpointed address.

The VNCR field in ESR_EL2 identifies whether the Watchpoint exception came from use of VNCR_EL2 by EL1, see ISS encoding for an exception from a Watchpoint exception on page D12-2801.

When in Debug state, or while using performance monitoring, Statistical Profiling, or permission checking, breakpoints, trace, and sampling of operations all treat the read and write of registers as executed at EL1.

When in Debug state, or while using performance monitoring, Statistical Profiling, or permission checking, the MMU and watchpoint unit treat the loads and stores generated by the transformation of reads and writes of registers as an EL2 access.

While using performance monitoring, any MRS or MSR instructions that have been transformed to loads or stores by this mechanism are treated as loads or stores.

When the Statistical Profiling Extension selects the instruction generating the memory access for profiling, Operation Type packet payload (Load/store) on page D9-2639 records the operation as a Load/Store operation, with a SUBCLASS value of 0b0000100x, where bit[0] is 0 for a load and 1 for a store.

When the Statistical Profiling Extension selects the instruction generating the memory access for profiling while Statistical Profiling is disabled at EL2, the virtual address for the memory access is not recorded.
D5.8 VMSAv8-64 memory aborts

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

**Debug exception**
An exception caused by the debug configuration, see Chapter D2 AArch64 Self-hosted Debug.

**Alignment fault**
An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see Alignment support on page B2-116.

**MMU fault**
An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MMU faults.

**External abort**
Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called aborts. Chapter D2 AArch64 Self-hosted Debug and on page H3-6455 describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

An access that causes an abort is said to be aborted, and uses the Fault Address Registers (FARs) and Exception Syndrome Registers (ESRs) to record context information.

In AArch64 state MMU faults are synchronous exceptions that are reported as either:
- Data Aborts.
- Instruction Aborts

--- Note ---
Instruction Aborts report any synchronous memory abort on an instruction fetch.

The Exception level that an MMU fault is taken to depends on the translation regime and stage that generated the fault. The fault context saved in the appropriate ESR_ELx, where ELx is the Exception level that the fault is taken to, is dependent on whether:
- The MMU fault is reported as an Instruction or as a Data Abort.
- The exception is taken from the same or a lower Exception level.

For more information, see Synchronous exception types, routing and priorities on page D1-2190.

External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError interrupt. For more information, see External aborts on page D4-2377.

Software stepping, which is a debug feature, and a PC alignment fault exception are the only exceptions that are higher priority than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For more information, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.

The following sections describe the abort mechanisms:
- Types of MMU faults.
- The MMU fault-checking sequence on page D5-2502.
- AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2506.
- Pseudocode description of the MMU faults on page D5-2508.

D5.8.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in The MMU fault-checking sequence on page D5-2502. The following list includes all the types of exceptions that can occur:
- Alignment fault on a data access, see Alignment support on page B2-116.
• Permission fault.
• Translation fault.
• Address size fault.
• Synchronous External abort on a translation table walk.
• Access flag fault.
• TLB conflict abort.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults that are not described elsewhere this Manual.

**Permission fault**

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About access permissions* on page D5-2456 for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that causes a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

• A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk*.

• When the value of SCTLR_EL1.UCI is 1, enabling EL0 execution of the DC CVAU, DC CVAC, DC CVAP, DC CIVAC, and IC IVAU instructions:
  — Executing a DC CVAU, DC CVAC, DC CVAP, or DC CIVAC instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault, subject to the constraints described in this section.
  — It is IMPLEMENTATION DEFINED whether executing an IC IVAU instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.

• A DC IVAC instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault, subject to the constraints described in this section.

  — Execution of the DCIVAC instruction in AArch32 state does not have this write permission requirement.
  — When EL1&0 stage 2 address translation is enabled, a DC IVAC instruction executed in Non-secure state performs a cache clean and invalidate, meaning it performs the same invalidation as a DC CIVAC instruction, as described in *Effects of virtualization and Security state on the cache maintenance instructions* on page D4-2369.

In all cases where the execution of a cache maintenance instruction might generate a Permission fault:

• If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA to the Point of Coherency instruction can generate a Permission fault.

• If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault.

The Data Cache Zero instruction, DC ZVA, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.
Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information, see VMSAv8-64 translation table format descriptors on page D5-2444.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a TTBR_ELx, or the TTBR_ELx range that it maps onto is disabled. In these cases, the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a TTBR_ELx failed.

A data or unified cache maintenance by VA instruction can generate a Translation fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate a Translation fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The TTBR_ELx used for the translation.
- A translation table entry.
- The output address of the translation.

For an Address size fault generated because the TTBR_ELx used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by VA instruction can generate an Address size fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate an Address size fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see Output address size on page D5-2400.
External abort on a translation table walk

An External abort on a translation table walk can be either synchronous or asynchronous. An External abort on a translation table walk is reported:

• If the external abort is synchronous, using:
  — A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
  — A synchronous Data Abort exception if the translation table walk is for a data access.

• If the External abort is asynchronous, using the SError interrupt exception.

Behavior of External aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in Address translation instructions on page C5-344 require translation table walks. An External abort can occur in the translation table walk. This is reported as follows:

• If the External abort is synchronous, using a synchronous Data Abort exception.

• If the External abort is asynchronous, using the SError interrupt exception.

For more information, see Synchronous faults generated by address translation instructions on page D5-2441.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see VMSAv8-64 translation table format descriptors on page D5-2444.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see The Access flag on page D5-2466.

D5.8.2 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

• If an instruction fetch faults, it generates an Instruction Abort.

• If a data memory access faults, it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see About address translation and supported input address ranges on page D5-2395.

——— Note ————

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in TLB conflict aborts on page D5-2513.

Types of MMU faults on page D5-2499 describes the faults that an MMU fault-checking sequence can report.

Figure D5-18 on page D5-2503 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.
Figure D5-18 Fetching the descriptor in a VMSAv8-64 translation table walk

Figure D5-19 on page D5-2504 shows the full VMSA fault checking sequence, including the alignment check on the initial access.
Figure D5-19: VMSAv8-64 fault checking sequence

1. Is the access subject to an alignment check?
2. Does the address map to a TTBR?
3. Not permitted at the lowest lookup level
4. Fault any unaligned access to Device memory
Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous External abort on the memory access.

If SCR_EL3.EA is set to 1, a synchronous External abort is taken to EL3. Otherwise, these faults are reported as stage 2 memory aborts. ESR_EL2.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-2172.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the HCR_EL2.PTW bit is set to 1, such an access generates a stage 2 Permission fault.

--- Note ---

On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

---

A TLB might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if HCR_EL2.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in EL1 or EL0 state. For more information, see Changing HCR_EL2.PTW on page D5-2532.

A cache maintenance instruction executed at EL1 or EL0 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault as described in this section. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.
- It is IMPLEMENTATION DEFINED whether an instruction cache invalidation by VA instruction can generate a Permission fault in this way.

--- Note ---

This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

The level associated with MMU faults

For MMU faults, Table D5-49 shows how the LL bits in the ESR_ELx.STATUS fields encode the lookup level associated with the fault.

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Level 0 of translation or translation table base register.</td>
</tr>
<tr>
<td>01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>11</td>
<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>
The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see *Synchronous External aborts from address translation caching structures* on page D5-2508

### D5.8.3 AArch64 state prioritization of synchronous aborts from a single stage of address translation

*Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191* describes the prioritization of exceptions taken to an Exception level that is using AArch64. This section gives additional information about the prioritization of MMU faults from VMSAv8-64 translation regimes.

---

**Note**

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-64 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in *AArch32 state prioritization of synchronous aborts from a single stage of address translation* on page G5-5555.

For a single stage of translation in a VMSAv8-64 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur*. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults:

  - For synchronous External aborts from translation table walks, see also *Synchronous External aborts from address translation caching structures* on page D5-2508.

  The prioritization between the stage 2 permission failure on the stage 1 translation table walk and the stage 1 abort generated by the stage 1 translation table entry is IMPLEMENTATION DEFINED if all the following are true:

    - Stage 1 hardware updating of either access or dirty information is enabled.
    - A stage 1 translation table entry results in the stage 1 translation table entry having the access or dirty bit updated.
    - The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.
    - The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a permission fault).

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a TTBR_ELx that is disabled. This includes VTCR_EL2.SL0 being inconsistent with VTCR_EL2.T0SZ, VSTCR_EL2.SL0 being inconsistent with VSTCR_EL2.T0SZ, or SL0 programmed to a reserved value.
3. Address size fault on a TTBR_ELx caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The PA being out of the range implemented.
4. Second stage abort on a level 0 memory access of a stage 1 table walk. When stage 2 address translation is enabled, this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

5. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.

6. Synchronous External abort on a level 0 lookup level of a translation table walk.

7. Translation fault on a level 0 translation table entry.

8. Address size fault a level 0 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

9. Second stage abort on a level 1 memory access of a stage 1 table walk. When stage 2 address translation is enabled, this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

10. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.

11. Synchronous External abort on a level 1 lookup level of a translation table walk.

12. Translation fault on a level 1 translation table entry.

13. Address size fault on a level 1 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

14. Second stage abort on a level 2 memory access of a stage 1 table walk. When stage 2 address translation is enabled, this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

15. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.

16. Synchronous External abort on a level 2 lookup level of a translation table walk.

17. Translation fault on a level 2 translation table entry.

18. Address size fault on a level 2 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

19. Second stage abort on a level 3 memory access of a stage 1 table walk. When stage 2 address translation is enabled, this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

20. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.

21. Synchronous External abort on a level 3 lookup level of a translation table walk.

22. Translation fault on a level 3 translation table entry.

23. Address size fault on a level 3 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

25. Alignment fault caused by the memory type.

26. Permission fault.

27. A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled, this includes an Address size fault caused by the PA being out of the range implemented.
28. Synchronous parity or ECC error on the memory access.
29. Synchronous External abort on the memory access.

--- Note ---

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

---

### Synchronous External aborts from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous External aborts arising from the caching structure, including parity or ECC errors, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.
- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  - The lowest-numbered level that could have given rise to the error.
  - Level 0 if it the PE cannot determine any information about the level.

---

### D5.8.4 Pseudocode description of the MMU faults

The following functions generate fault records that describe MMU faults:

- `AArch64.AccessFlagFault()`.  
- `AArch64.AddressSizeFault()`.  
- `AArch64.PermissionFault()`.  
- `AArch64.TranslationFault()`.

*Abort exceptions on page D4-2382* describes how fault records are used.
Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

--- Note ---
The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

Note
In addition to the functions described in this section, the TLB might cache information from control registers that are described as being “permitted to be cached in a TLB”, even when any or all of the stages of translation are disabled. This caching of information gives rise to the maintenance requirements described in General TLB maintenance requirements on page D5-2515.

---

## D5.9.1 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID, as follows:

**ASID**
For stage 1 of a translation regime that can support two VA ranges the VMSA can distinguish between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

For these stage 1 translations, each of TTBR0_ELx and TTBR1_ELx has a valid ASID field, and TCR_ELx.A1 determines which of these holds the current ASID.

--- Note ---
The selected ASID applies regardless of which set of translation tables are used. For example, when the value of TCR_ELx.A1 is 0, any translation table lookup using this stage of translation is associated with the ASID from TTBR0_ELx.ASID, regardless of whether the translation lookup uses TTBR0_ELx or TTBR1_ELx.

---

See also *ASID size* on page D5-2510 and *Global and process-specific translation table entries* on page D5-2512.

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

**VMID**
For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another if the virtual machines have different VMIDs. VTTBR_EL2.VMID holds the current VMID.
Common not private translations

In an implementation that includes ARMv8.2-TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of translation in a particular translation regime. This sharing is enabled by the TTBR_ELx.CnP field for the stage of address translation.

When the value of a TTBR_ELx.CnP field is 1, translation table entries pointed to by that TTBR_ELx are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding TTBR_ELx.CnP field has the value 1.
- That TTBR_ELx relates to the same translation regime.

--- Note ---

- For TTBR0_EL1 the current Security state determines whether the register relates to the Secure EL1&0, when EL2 is disabled, translation regime, or to the Non-secure EL1&0, when EL2 is enabled, translation regime.
- For TTBR0_EL2 the value of HCR_EL2.E2H determines whether the register relates to the EL2 translation regime, or to the EL2&0 translation regime.

---

- If an ASID applies to the stage of translation corresponding to that TTBR_ELx then the current ASID value must be the same for all of the PEs that are sharing entries for any translation table entry that is not global or leaf level.
- If a VMID applies to the stage of translation corresponding to that TTBR_ELx then the current VMID value must be the same for all of the PEs that are sharing entries.

Where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR_ELx.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR_ELx.CnP bit can be cached in a TLB.

For a given TTBR_ELx, if the value of TTBR_ELx.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBR_ELxs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR_ELx:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page D5-2513.
- Otherwise, has a CONSTRAINED UNPREDICTABLE result, as described in CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.

ASID size

In VMSAv8-64, the ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID_AA64MMFR0_EL1.ASIDBits identifies the supported size.

When an implementation supports a 16-bit ASID, TCR_ELx.AS selects whether the top 8 bits of the ASID are used. When the value of TCR_ELx.AS is 0, ASID[15:8]:

- Are ignored by hardware for every purpose other than direct reads of TTBR0_ELx.ASID and TTBR1_ELx.ASID.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.
D5.9 Translation Lookaside Buffers (TLBs)

**Note**

VMSA v8-32 uses an 8-bit ASID. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the ASID size remains at 8 bits. If the implementation supports 16-bit ASIDs, the 8-bit ASID used is zero-extended to 16 bits.

**VMID size**

From ARMv8.1, the VMID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID_AA64MMFR1_EL1.VMIDBits identifies the supported size.

When ARMv8.1-VMID16 is implemented, VTTBR_EL2[63:48] contains the 16-bit VMID.

When an implementation supports a 16-bit VMID, VTCR_EL2.VS selects whether the top 8 bits of the VMID are used.

When the value of VTCR_EL2.VS is 0, VMID[63:56]:
- Are ignored by hardware for every purpose other than reads of ID_AA64MMFR1_EL1.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

ARMv8.1-VMID16 is only supported when EL2 is using AArch64.

**D5.9.2 About ARMv8 Translation Lookaside Buffers (TLBs)**

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in a TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

**Note**

A TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- *Global and process-specific translation table entries on page D5-2512.*
- *TLB matching on page D5-2512.*
- *TLB behavior at reset on page D5-2513.*
Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by a stage of translation that can support two VA ranges into global and non-global regions, indicated by the nG bit in the translation table descriptors:

\[ nG = 0 \]

The translation is global, meaning the region is available for all processes.

\[ nG = 1 \]

The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:

- TTBR0_ELx.ASID, if the value of TCR_ELx.A1 is 0.
- TTBR1_ELx.ASID, if the value of TCR_ELx.A1 is 1.

As indicated by the nG field definitions, each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

Note

- The selected ASID applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on TTBR0_ELx or on TTBR1_ELx.
- In an implementation that does not include ARMv8.1-VHE, the only stage of translation that can support two VA ranges is stage 1 of the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE stage 1 of the EL2&0 translation regime also can support two VA ranges.

ASIDs are supported only when stage 1 translations can support two VA ranges. Stage 2 translations, and stage 1 translations that can support only a single VA range do not support ASIDs, and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information, see Control of Secure or Non-secure memory access on page D5-2455.

TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in TLB maintenance requirements and the TLB maintenance instructions on page D5-2515 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in Using break-before-make when updating translation table entries on page D5-2516 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page D5-2513.
Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.

TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information, see Controlling address translation stages on page D5-2397.
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in TLB maintenance instructions on page D5-2518.

Similar rules apply to cache behavior, see Behavior of caches at reset on page D4-2359.

TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the System instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D11-2671. An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

In an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in EL1 or EL0 state can be routed to either:

- EL1, as a Data Abort exception.
- EL2, as a Hyp Trap exception.

For more information, see Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-2225.

TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.
An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort:

• On an instruction fetch is reported as an Instruction Abort, see ISS encoding for an exception from an Instruction Abort on page D12-2790.
• On a data access is reported as a Data Abort, see ISS encoding for an exception from a Data Abort on page D12-2792.

ARMv8 defines the Fault status encoding of 0b110000 for TLB conflict aborts. On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

It is implementation defined whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

A stage 2 abort cannot be generated if stage 2 of the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is disabled.

The priority of the TLB conflict abort is implementation defined, because it depends on the form of a TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort is generated, the resulting behavior is constrained unpredictable, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218. The constrained unpredictable behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.
D5.10 TLB maintenance requirements and the TLB maintenance instructions

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- General TLB maintenance requirements.
- TLB maintenance instructions on page D5-2518.

See also:
- Maintenance requirements on changing System register values on page D5-2531.
- Atomicity of register changes on changing virtual machine on page D5-2405.

D5.10.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk.
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for a translation regime that involves two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

Note

For the purpose of TLB maintenance, the term TLB entry denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

Note

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
- As stated in Global and process-specific translation table entries on page D5-2512, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.
• Required to apply to stage 2 entries only, then:
  — It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  — It must apply to caching structures that contain information only from stage 2 translation table entries.

• Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular VMID or ASID are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some System register field descriptions state that the effect of the field is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change of the field must be invalidated whenever that field is changed, to ensure that the effect of the change of that control field is visible to subsequent execution, including speculative execution, that uses that control field. This invalidation is required in addition to, and after, the normal synchronization of the System registers described in Synchronization requirements for AArch64 System registers on page D12-2675, and applies to any stage of address translation that is implemented for the translation regime, and VMID and ASID as appropriate, that is affected by that control field. A control field that is permitted to be cached in a TLB requires this maintenance even when all stages of address translation are disabled.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see Cache maintenance requirement created by changing translation table attributes on page D5-2535.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB invalidation. However, a Context synchronization event is required to ensure that instruction fetches are affected by a completed change to translation table entries that, before the change, generated a Translation, Address size, or Access flag fault.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see Using break-before-make when updating translation table entries.

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

• A change of the memory type.

• A change of the cacheability attributes.

• A change of the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable, including if the DBM bit is set and hardware updates to the dirty bits are enabled.

• A change to the size of block used by the translation system. This applies both:
  — When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
  — When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.

• Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.
A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a `DSB` instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a `DSB` instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a `DSB` instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

In ARMv8.1, with the introduction of hardware updates to the translation table entries, the effects of not following the break-before-make rules are extended.

If the break-before-make rules are not followed for changing the translation table entries, the ARMv8.1 architecture permits that the following failures associated with the hardware updates of the translation table entries could occur:

- The Access flag is not set on such a translation table entry despite the fact that the memory location associated with that entry was accessed.
- The AP[2] or S2AP[1] bit is modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was not written to.
- The AP[2] or S2AP[1] bit is not modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was written to.
- The ordering required between hardware updates to such a translation table entry and stores appearing later in program order is not followed.

**Support levels for changing block size**

If ARMv8.4-TTRem is implemented, the PE provides three levels of support when changing block size, without changing any other parameters that require break-before-make:

- **Level 0** Software must use break-before-make to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors when changing block size. See *Using break-before-make when updating translation table entries* on page D5-2516.
- **Level 1** Software can use the level 0 approach, or software can use the nT block translation entry to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors when changing block size. See *Block translation entry* on page D5-2467.
- **Level 2** Software can use the level 0 or level 1 approach and, in addition, changing block size does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors. If there has not been a TLB invalidation of the entries that have changed since the writes that changed those entries were completed, this change might cause Conflict aborts. This is because multiple translation entries might exist within the TLB for the same input address.

In addition, an implementation that uses the level 1 or level 2 approach supports the following without breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors:

- A change to a set of blocks or pages from having the Contiguous bit set to having the Contiguous bit not set.
- A change to a set of blocks or pages from having the Contiguous bit not set to having the Contiguous bit set.

If multiple translation entries exist within the TLB for the same input address, this change might cause Conflict aborts when translating the address.

If a Conflict abort is detected in a translation regime for which stage 2 translations are enabled, the Conflict abort is reported to EL2.
Clearing entries associated with a Conflict abort

While using level 1 or level 2 support, on a Conflict abort, the following instructions are guaranteed to clear the entries associated with the conflict:

- For the EL1&0 Translation regime, while stage 2 translations are in use: `TLBI VMALLS12E1, TLBI ALLE1.`
- For the EL1&0 Translation regime, while stage 2 translations are not in use: `TLBI VMALLE1, TLBI ALLE1.`
- For the EL2&0 Translation regime: `TLBI VMALLE1, TLBI ALLE1.`
- For the EL2 Translation regime: `TLBI ALLE2.`
- For the EL3 Translation regime: `TLBI ALLE3.`

D5.10 TLB maintenance instructions

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Invalidate all TLB entries within a range of addresses.

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same shareability domain as the PE that executes the instruction.

The following subsubsections describe these instructions:

- **TLB maintenance instruction syntax.**
- **Operation of the TLB maintenance instructions on page D5-2522.**
- **Scope of the A64 TLB maintenance instructions on page D5-2523.**
- **TLB range maintenance instructions on page D5-2526.**
- **Invalidation of TLB entries from stage 2 translations on page D5-2526.**
- **Broadcast TLB maintenance between AArch32 and AArch64 on page D5-2528.**
- **Broadcast TLB maintenance with different translation granule sizes on page D5-2529.**
- **Ordering and completion of TLB maintenance instructions on page D5-2530.**
- **TLB maintenance in the event of TLB conflict on page D5-2530.**
- **The interaction of TLB lockdown with TLB maintenance instructions on page D5-2531.**

**TLB maintenance instructions on page C5-344** describes the encoding of the TLB maintenance instructions.

### TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

```plaintext
TLBI <operation>{, <Xt>}  
```

Where:

- `<operation>` is one of `ALLE1, ALLE2, ALLE3, ALLE1IS, ALLE1OS, ALLE2IS, ALLE2OS, ALLE3IS, ALLE3OS, VMALLE1, VMALLE1IS, VMALLE1OS, VMALLS12E1, VMALLS12E1IS, VMALLS12E1OS, ASIDE1, ASIDE1IS, ASIDE1OS, (R)VA(L)E1, (R)VA(L)E2, (R)VA(L)E3, (R)VA(L)E1IS, (R)VA(L)E1OS, (R)VA(L)E2IS, (R)VA(L)E2OS, (R)VA(L)E3IS, (R)VA(L)E3OS, (R)IPAS2(L)E1, (R)IPAS2(L)E1IS, or (R)IPAS2(L)E1OS.
- `<operation>` has a structure of (R)<type><level><shareability> where:
  - **R** When present, indicates that the function applies to all TLBs that are within a determined address range, see **TLB range maintenance instructions on page D5-2526.**
  - When not present, indicates that the function applies to all TLBs at a single address that contain entries that could be used by the PE that executes the TLBI instruction.
- `<type>` is one of:
  - **ALL** All translations used at `<level>`.
For the scope of ALL instructions see ALL on page D5-2523.
The ALL instructions are valid for all values of <level>.

**VMALL**
All stage 1 translations used at <level> with the current VMID, if appropriate.
For the scope of the VMALL instructions see VMALL on page D5-2523.
The VMALL instructions are valid only when level == E1.

**VMALLS12**
All stage 1 and stage 2 translations used at EL1 with the current VMID, if appropriate.
For the scope of the VMALLS12 instructions see VMALLS12 on page D5-2523.
The VMALLS12 instructions are valid only when level == E1.

**ASID**
All translations used at EL1 with the supplied ASID.
For the scope of the ASID instructions see ASID on page D5-2524.
The ASID instructions are valid only when level == E1.

**VA(L)**
Translations used at <level> for the specified address and, if appropriate, the specified ASID.
For the scope of the VA instructions see VA on page D5-2524. For the scope of the VAL instructions see VAL on page D5-2524.
The VA(L) instructions are valid for all values of <level>.

**VAA(L)**
Translations used at <level> for the specified address, for all ASID values, if appropriate.
For the scope of the VAA instructions see VAA on page D5-2525. For the scope of the VAAL instructions see VAAL on page D5-2525.
The VAA(L) instructions are valid only when level == E1.

**IPAS2(L)**
Translations used at <level> for the specified IPA that are held in stage 2 only caching structures.
For the scope of the IPAS2 instructions see IPAS2 on page D5-2525. For the scope of the IPAS2L instructions see IPAS2L on page D5-2525.
The IPAS2(L) instructions are valid only when level == E1.

In the VA(L), VAA(L), and IPAS2(L) types:

**L**
An optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.

**<level>**
Defines the Exception level of the translation regime that the invalidation applies to. Is one of:

- E1  EL1.
- E2  EL2.
- E3  EL3.

An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is UNDEFINED.

**TLBI ALLE1{IS}, TLBI IPAS2{L}E1{IS} and TLBI VMALLS12E1{IS}** are UNDEFINED at EL1.

---

**Note**
All TLB maintenance instructions are UNDEFINED at EL0.

---

**<shareability>**
Is one of:

- IS  When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain.
- OS  When present, it indicates that the function applies to all TLBs in the Outer Shareable shareability domain.
When no shareability is present, it indicates that the function applies to all TLBs that contain entries that could be used by the PE that executes the TLBI instruction.

--- Note ---
When a TLB entry has been invalidated for one PE, it is not consistent with the architecture to allow another PE to refill that TLB entry where the new entry might give the appearance to software that the invalidation has not occurred.

<xref></xref> Passes one or both of an address and an ASID as an argument, where required. <xref> is required for the TLB ASID, TLB VA(L), TLB VAa(L), and TLB IPAS2(L) instructions.

If EL2 is not implemented, the TLBI VA(L)E2, TLBI VA(L)E2IS, TLBI ALLE2, and TLBI ALLE2IS instructions are UNDEFINED.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a VA, an ASID, or both, and that do not apply to a range of addresses, use the register argument format:

- **Bits[63:48]** ASID. These bits are RES0 if the instruction does not require an ASID argument.
- **Bits[47:44]** TTL. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated, see *Translation table level hints on page D5-2521*. This field is RES0 if the instruction does not require a VA argument, or if ARMv8.4-TTL is not implemented.
- **Bits[43:0]** VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
  - **4KB granule size** All bits are valid and used for the invalidation.
  - **16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
  - **64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address argument, hardware interprets VA[63:56] as each having the same value as VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID are RES0 when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an IPA, and that do not apply to a range of addresses, use the register argument format:

- **Bits[63:48]** RES0.
- **Bits[47:44]** TTL. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated, see *Translation table level hints on page D5-2521*. This field is RES0 if the instruction does not require an IPA argument, or if ARMv8.4-TTL is not implemented.
- **Bits[43:36]** RES0.
- **Bits[35:0]** IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
  - **4KB granule size** All bits are valid and used for the invalidation.
  - **16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
  - **64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

For the register argument format of TLB instructions that apply to a range of addresses, see *TLB range maintenance instructions on page D5-2526*. 
Translation table level hints

When ARMv8.4-TTL is implemented, the TTL field indicates the level of page table walk holding the leaf entry for the address being invalidated. Hardware can use this information to determine if there was a risk of splintering.

If an incorrect value for the entry being invalidated by the instruction is specified in the TTL field, then no entries are required by the architecture to be invalidated from the TLB.

The TTL field in TLB maintenance instructions that take a register argument that holds a VA or an IPA, and that do not apply to a range of addresses, use the encodings in Table D5-50.

<table>
<thead>
<tr>
<th>TTL[3:2]</th>
<th>TTL[1:0]</th>
<th>Information supplied</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>RES0</td>
<td>No information supplied about the translation level. Hardware must assume that the entry can be from any level.</td>
</tr>
<tr>
<td>01</td>
<td>00</td>
<td>The entry comes from a 4KB translation granule. This value is reserved, and hardware should treat this as if TTL[3:2] is 0b00.</td>
</tr>
<tr>
<td>01</td>
<td>01</td>
<td>The entry comes from a 4KB translation granule. The leaf entry for the address being invalidated is on level 1 of the page table walk.</td>
</tr>
<tr>

</tr>
<tr>
<td>10</td>
<td>All entries to invalidate are Level 2 translation table entries.</td>
</tr>
<tr>
<td>11</td>
<td>All entries to invalidate are Level 3 translation table entries.</td>
</tr>
</tbody>
</table>

**Operation of the TLB maintenance instructions**

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

**Note**

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.

- **SCR_EL3.NS** modifies the effect of the TLB maintenance instructions as follows:
  
  - For instructions that apply to the EL1&0 translation regime, the SCR_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

  **Note**

  If EL3 is not implemented, then there is only a single EL1&0 translation regime.

  - When SCR_EL3.EEL2 is 0 instructions that apply to the EL2 translation regime, or to the EL2&0 translation regime, the SCR_EL3.NS bit must be 1 or the instruction is UNDEFINED.
  
  - For instructions that apply to the EL3 translation regime, the SCR_EL3.NS bit has no effect.

**Note**

- An address-based TLB maintenance instruction that applies to the Inner Shareable domain or the Outer Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

- Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
  
  - AArch64 state does not include any of these instructions.
  
  - AArch32 state includes some of these instructions, but ARM deprecates their use.
The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

--- Note ---
The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB.

Scope of the A64 TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible cached entries in the TLB as follows:

**ALL**
The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by SCR_EL3.NS and SCR_EL3.EEL2.

For entries from the Secure or Non-secure EL1&0 translation regime, when EL2 is enabled, ALL applies to entries with any VMID.

For entries from a translation regime for which an ASID is valid, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

--- Note ---
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

**VMALL**
The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

--- Note ---
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

**VMALLS12**
The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to:

- All entries above the final level of lookup.
• All entries at the final level of lookup.

Note
This means the invalidation applies to both:
— Global entries.
— Non-global entries with any ASID.

VMALLS12 is valid for EL1.

If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed when the value of SCR_EL3.NS is 0 and EL2 is disabled, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.

ASID

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
• The Security state specified by SCR_EL3.NS and SCR_EL3.EEL2.
• For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if either:
• The entry is from a level of lookup above the final level and matches the specified ASID.
• The entry is a non-global entry from the final level of lookup and matches the specified ASID.

ASID is valid for:
• EL1.
• EL2, when HCR_EL2.{E2H, TGE} is {1, 1}.

VA

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:
• The Security state specified by SCR_EL3.NS and SCR_EL3.EEL2.
• For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if one of the following applies:
• The entry is from a level of lookup above the final level and matches the specified ASID.
• The entry is a global entry from the final level of lookup.
• The entry is a non-global entry from the final level of lookup that matches the specified ASID.

VAL

The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with all of:
• The Security state specified by SCR_EL3.NS and SCR_EL3.EEL2.
• For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if either:
• The entry is a global entry from the final level of lookup.
• The entry is a non-global entry from the final level of lookup that matches the specified ASID.
VAA
The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to all of:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

Note
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

VAAL
The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- For the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to all entries at the final level of lookup.

Note
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

IPAS2
The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.

When executed with the SCR_EL3.NS == 0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2 instruction see Invalidation of TLB entries from stage 2 translations on page D5-2527.

IPAS2L
The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime.

When executed with the SCR_EL3.NS == 0, or in an implementation that does not implement EL2, this instruction is a NOP.
For more information about the architectural requirements for the IPAS2L instruction see Invalidation of TLB entries from stage 2 translations on page D5-2527.

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

**In AArch64 state**

TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, TCR_EL2.{TG0, T0SZ},
TCR_EL3.{TG0, T0SZ}, VTCR_EL2.{SL0, T0SZ}, TTBR0_EL1.ASID, TTBR1_EL1.ASID.

**In AArch32 state**

SCTLR.M, HCR.VM, TTBCR.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1},
HTCR.T0SZ, VTCR.{SL0, T0SZ}, TTBR0.ASID, TTBR1.ASID, CONTEXTIDR.ASID.

**Note**

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.

- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.

- Dependencies on the VMID for the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime apply even when the value of HCR_EL2.VM is 0. The VTTBR_EL2.VMID field resets to a value that is architecturally UNKNOWN, and therefore VTTBR_EL2.VMID[7:0] must be set to a known value, that might be zero, as part of the PE initialization sequence, even if stage 2 translation is not in use.

**TLB range maintenance instructions**

Specific TLB invalidation instructions apply to a range of input addresses rather than a single address. All TLB range maintenance instructions invalidate TLB entries that are within the address range determined by the formula:

\[
\text{BaseADDR} \leq \text{input_address} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^5 \times \text{Translation Granule Size})
\]

**Note**

The set of masters containing TLBs that can be affected by the TLB range maintenance instructions are defined by the system architecture. This means that all masters in a system might not contain TLBs within the defined shareability domains.

VMSA\text{v8-64} TLB range maintenance instructions that take a register argument that holds a VA, or a VA and an ASID, use the following register argument format:

**Bits[63:48]** ASID. These bits are RES0 if the instruction does not require an ASID argument.

**Bits[47:46]** TG. This field gives the translation granule size for the translations that are being invalidated. If the translations use a different translation granule size than the one specified, then the architecture does not require that the instruction invalidates any entries.

**Bits[45:44]** SCALE. This field gives the exponent element of the calculation that is used to produce the upper range.

**Bits[43:39]** NUM. This field gives the base element of the calculation that is used to produce the upper range.
Bits[38:37] TTL level hint, see Translation table level hints on page D5-2521. This field is RES0 if the instruction does not require a VA argument, or if ARMv8.4-TTL is not implemented.

Bits[36:0] BaseADDR. This field gives the starting address for the range of the maintenance instruction.

4KB granule size BaseADDR[48:12].
16KB granule size BaseADDR[50:14].
64KB granule size BaseADDR[52:16].

VMSAv8-64 TLB range maintenance instructions that take a register argument that holds an IPA, use the following register argument format:

Bits[63] NS. This bit is RES0 if the instruction is executed in Non-secure state.

Bits[62:48] RES0.

Bits[47:46] TG. This field gives the translation granule size for the translations that are being invalidated. If the translations use a different translation granule size than the one specified, then the architecture does not require that the instruction invalidates any entries.

Bits[45:44] SCALE. This field gives the exponent element of the calculation that is used to produce the upper range.

Bits[43:39] NUM. This field gives the base element of the calculation that is used to produce the upper range.

Bits[38:37] TTL level hint, see Translation table level hints on page D5-2521. This field is RES0 if the instruction does not require a VA argument, or if ARMv8.4-TTL is not implemented.

Bits[36:0] BaseADDR. This field gives the starting address for the range of the maintenance instruction.

4KB granule size BaseADDR[48:12].
16KB granule size BaseADDR[50:14].
64KB granule size BaseADDR[52:16].

The range of addresses invalidated is UNPREDICTABLE when:

- When a 4K translation granule used, if the TTL field is 0b01 and BaseADDR[29:12] does not equal 0b000000000000000000.
- When a 4K translation granule used, if the TTL field is 0b10 and BaseADDR[20:12] does not equal 0b00000000.
- When a 16K translation granule used, if the TTL field is 0b10 and BaseADDR[24:12] does not equal 0b0000000000.
- When a 64K translation granule used, if the TTL field is 0b01 and BaseADDR[41:16] does not equal 0b00000000000000000000000000.
- When a 64K translation granule used, if the TTL field is 0b10 and BaseADDR[28:16] does not equal 0b00000000000.

Invalidation of TLB entries from stage 2 translations

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the IPA held in Xt for the current VMID, with the corresponding requirement for the broadcast versions of the instructions:
   TLBI IPAS2E1, Xt
   DSB
   TLBI VMALLE1

2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the VA (and the specified ASID when executing TLBI VÆE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:
TLBI IPAS2E1, Xt
TLBI VA1E1, Xt2 ; or TLBI VAA1E1, Xt2

3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the IPA produced by the last level of stage 1 translation table lookup for the VA (and ASID when executing TLBI VA1E1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

TLBI IPAS2E1, Xt
TLBI VA1E1, Xt2 ; or TLBI VAA1E1, Xt2

--- Note ---

Depending on the invalidation required, software must use the entire sequence 1, 2, or 3, even when Secure or Non-secure EL1&0, when EL2 is enabled, stage 1 translation is disabled.

--- Note ---

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.

**Broadcast TLB maintenance between AArch32 and AArch64**

In most cases, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the ASID and VMID matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions* on page D5-2523.

--- Note ---

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If VA matching is required, the VA is 0x0000FFFFFFFF or lower in the memory map.
- If ASID matching is required and the PE is using a 16-bit ASID, then the top 8 bits of the ASID are zero.

--- Note ---

Except for the cases identified here, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, ASID, and VMID matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions* on page D5-2523. In addition, for the instruction executed in AArch32 state:

- For a TLBIMVA1IS, TLBIMVAALIS, TLBIMVAPIS, TLBIMVA2IS, TLBIMVAPALIS, or TLBIMVALIS instruction, the VA supplied as an argument is zero-extended.
- For a TLBIIPAS2IS or TLBIIPAS2LIS instruction, the IPA supplied as an argument is zero-extended.
- For a TLBIASIDIS, TLBIASIDS, or TLBIASD2IS instruction, the ASID supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.

The VA from the instruction executed in AArch32 state is zero-extended, and the ASID is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.
The exceptions to these general rules are as follows:

1. An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues a broadcast instruction that is not defined in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:
   - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:
     - TLBIMVALIS
     - TLBIMVAALIS
     - TLBIMVALHIS
     - TLBIMVAL
     - TLBIMVAAL
     - TLBIMVALH.
   - The following instructions that operate by IPA on TLB entries for stage 2 translations:
     - TLBIIPAS2IS
     - TLBIIPAS2LIS
     - TLBIIPAS2
     - TLBIIPAS2L.

2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Shareable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:
   - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
     - The EL3 translation regime of the PEs with EL3 using AArch64.
     - The Secure or Non-secure EL1&0, when EL2 is disabled, translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure or Non-secure EL1&0, when EL2 is disabled, translation regime is using AArch64 or AArch32.
   - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.
   - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

   **Note**
   While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

### Broadcast TLB maintenance with different translation granule sizes

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

- The TLB maintenance instruction specifying a VA and affecting the EL2 translation regime, the EL2&0 translation regime, or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime.
- The TLB maintenance instruction specifying a VA and affecting the EL1&0 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular ASID (if applicable), VMID (if applicable), and Security state, to a PE where EL1 for the same ASID (if applicable), VMID (if applicable), and Security state, is using a different stage 1 translation granule size.
- The TLB maintenance instruction specifying a VA and affecting the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is broadcast from a PE using one stage 2 translation granule size for a particular ASID (if applicable) and VMID, to a PE where EL1 for the same ASID (if applicable) and VMID is using a different stage 2 translation granule size.
• The TLB maintenance instruction specifying an IPA and affecting the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime is broadcast from a PE using one stage 2 translation granule size for a particular VMID to a PE where EL1 for the same VMID is using a different stage 2 translation granule size.

**Ordering and completion of TLB maintenance instructions**

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

• Any load or store instruction, unless a DSB is executed between the load or store and the TLB maintenance instruction.

        **Note**

In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to the translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the store to the translation tables.

• Another TLB maintenance instruction, unless a DSB is executed between the instructions.

• A data or instruction cache maintenance instruction, unless a DSB is executed between the instructions.

For AArch64 execution, the completion rules are:

• A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

        **Note**

This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible for software running on any observer to tell that those memory accesses have been performed.

• A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of DSB by the PE that executed the TLB maintenance instruction.

• The effects of a completed TLB maintenance instruction are only guaranteed to be visible on the PE that executed the instruction after the execution of a Context synchronization event by the PE that executed the TLB maintenance instruction.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

**TLB maintenance in the event of TLB conflict**

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.
The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The operation has no effect on entries that are locked down.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.
  Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-2225.

  **Note**

These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The locked entry is invalidated in the TLB.
  - The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a NOP.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see ESR_EL1, Exception Syndrome Register (EL1) on page D12-2770.

  **Note**

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page D4-2375.

**Note**

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

### D5.10.3 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB entries associated with a translation regime affected by these control bits must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID, if appropriate depending on the translation regime, that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:
; Change control bits in System registers
ISB     ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits

The System register changes that maintenance requirement applies to are:

- Any change to the MAIR_EL1, MAIR_EL2, or MAIR_EL3 registers.
- Any change to the AMAIR_EL1, AMAIR_EL2, or AMAIR_EL3 registers.
- Any change to SCTLR_EL1.EE, SCTLR_EL2.EE, or SCTLR_EL3.EE.
- Any change to SCTLR_EL1.WXN, SCTLR_EL2.WXN, or SCTLR_EL3.WXN.
- Any change to any of the SCR_EL3.{RW, SIF} bits.
- Any change to any of the HCR_EL2.{RW, DC, PTW, VM, NV1, NV, E2H} bits. See also Changing HCR_EL2.PTW.
- Any changes to the registers that control address translation:
  - Any change to any of the TCR_EL1, TCR_EL2, TCR_EL3, or VTCR_EL2 registers.
  - Any change to the TTBR0_EL1, TTBR1_EL1, TTBR1_EL2, TTBR0_EL2, TTBR0_EL3, or VTTBR_EL2 registers.

### Changing HCR_EL2.PTW

When the value of the Protected table walk bit, HCR_EL2.PTW, is 1, a stage 1 translation table access in the Secure or Non-secure EL1&0, when EL2 is enabled, translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if the value of HCR_EL2.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software at Non-secure EL1 or EL0. If this is not done, behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.
D5.11 Caches in a VMSAv8-64 implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

• Summarizes the architectural requirements for the interaction between caches and address translation.
• Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

• Data and unified caches.
• Instruction caches.

In addition, Cache maintenance requirement created by changing translation table attributes on page D5-2535 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see A64 Cache maintenance instructions on page D4-2364, that describes the cache maintenance instructions in the A64 instruction set.

D5.11.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access other than as described in Mismatched memory attributes on page B2-132.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

• Two writes to the same PA occur in program order.
• A read of a PA returns the value of the last successful write to that PA.
• A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.

D5.11.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

• P1PT (Physically-indexed, physically-tagged) instruction caches on page D5-2534.
• VPIPT (VMID-aware PIPT) instruction caches on page D5-2534.
• VIPT (Virtually-indexed, physically-tagged) instruction caches on page D5-2534.
• The IVIPT Extension on page D5-2535.

The CTR_EL0.L1Ip field identifies the form of the instruction caches.
Note

For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT (Physically-indexed, physically-tagged) instruction caches

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in Mismatched memory attributes on page B2-132.
- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see The IVIPT Extension on page D5-2535.

VPIPT (VMID-aware PIPT) instruction caches

An ARMv8.2 implementation can implement VPIPT instruction caches. If it does so then it is described as implementing ARMv8.2-VPIPT.

The CTR_EL0.L1Ip field identifies the implemented cache type, meaning it identifies whether ARMv8.2-VPIPT is implemented.

For a VPIPT instruction cache:

- Instruction fetches from Non-secure EL1 and Non-secure EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.
- An instruction cache maintenance instruction executed at Non-secure EL0 or at Non-secure EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for PIPT (Physically-indexed, physically-tagged) instruction caches.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see The IVIPT Extension on page D5-2535.

VIPT (Virtually-indexed, physically-tagged) instruction caches

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in Mismatched memory attributes on page B2-132.

Note

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the VA supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see The IVIPT Extension on page D5-2535.
The IVIPT Extension

In ARMv8, any permitted instruction cache implementation can be described as implementing the *IVIPT Extension* to the ARM architecture.

The formal definition of the ARM IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a PA that holds an instruction.

**Note**

Previous versions of the ARM architecture have permitted an instruction cache option that does not implement the ARM IVIPT Extension.

D5.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in *General TLB maintenance requirements on page D5-2515*. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from the cache.
3. Change the shareability attributes to the required new values.

Chapter D6
The Performance Monitors Extension

This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the Performance Monitor Unit (PMU) architecture, PMUv3. It contains the following sections:

• About the Performance Monitors on page D6-2538.
• Accuracy of the Performance Monitors on page D6-2540.
• Behavior on overflow on page D6-2542.
• Attributability on page D6-2544.
• Effect of EL3 and EL2 on page D6-2545.
• Event filtering on page D6-2547
• Performance Monitors and Debug state on page D6-2549.
• Counter enables on page D6-2550.
• Counter access on page D6-2551.
• PMU events and event numbers on page D6-2553.
• Performance Monitors Extension registers on page D6-2585.

Note
Table K13-2 on page K13-7396 disambiguates the general register references used in this chapter.
D6.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an optional feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

--- Note ---
No previous versions of the Performance Monitors Extension can be implemented in ARMv8.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see Time as measured by the Performance Monitors cycle counter on page D6-2539.

- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is implementation defined, and the specification includes an identification mechanism.

--- Note ---
ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

- When EL2 is implemented and enabled in the current Security state, the required controls to partition the implemented counters into the following sets:
  - A set which is available for use by the guest operating system.
  - A set which is available for use by the hypervisor.

--- Note ---
ARMv8.3-NV does not introduce any changes to the Performance Monitors, see Nested virtualization on page D5-2492.

- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.

Monitoring software can enable the cycle counter independently of the event counters.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

--- Note ---
Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See Common event numbers on page D6-2558.

- Reserves a large event number space for implementation defined events.

The full set of events for an implementation is implementation defined. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

--- Note ---
In AArch32 state, the interface is in the (coproc==0b1111) encoding space.
An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See Chapter 13 Recommended External Interface to the Performance Monitors.

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, PMCCNTR_EL0.
- When executing in AArch32 state, PMCCNTR.

### D6.1.1 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through PMCCNTR_EL0 or PMCCNTR, increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

**Note**

- This means that, in an implementation where PEs are multithreaded, the counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of PMCCNTR_EL0 or PMCCNTR occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the PMCCNTR_EL0 or PMCCNTR is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

### D6.1.2 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a PE Trace Unit, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the PE Trace Unit to pass in events to be counted.

### D6.1.3 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the \texttt{WFI} and \texttt{WFE} instructions.
D6.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See Non-invasive behavior.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See A reasonable degree of inaccuracy.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D6.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

Note

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

ARM does not define a reasonable variation in performance, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

Note

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative implementation defined event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an implementation defined control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

D6.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a reasonable degree of inaccuracy but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.

Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

**Note**

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can also affect the accuracy of the Performance Monitors, see *Interaction with EL3* on page D6-2545.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.
D6.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, PMCCNTR, is a 64-bit wrapping counter, that is configured by PMCR.LC to either:

- Signal an overflow when bit PMCCNTR[63] overflows.
- Signal an overflow when bit PMCCNTR[31] overflows into bit PMCCNTR[32].

On a Performance Monitors counter overflow:

- An overflow status bit is set to 1. See PMOVSCLR.
- An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see Generating overflow interrupt requests.
- The counter continues counting events.

D6.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See PMINTENSET and PMINTENCLR.

--- Note ---

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- ARM recommends that the overflow interrupt requests:
  - Translate into a PMUIRQ signal, so that they are observable to external devices.
  - Connect to inputs on an IMPLEMENTATION DEFINED generic interrupt controller as a Private Peripheral Interrupt (PPI) for the originating processor. See the ARM Generic Interrupt Controller Architecture Specification for information about PPIs.
  - Connect to a Cross Trigger Interface (CTI), see Chapter H5 The Embedded Cross-Trigger Interface.
- ARM strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same System Peripheral Interrupt (SPI) identifier.
- From GICv3, the ARM® Generic Interrupt Controller Architecture Specification recommends that the Private Peripheral Interrupt (PPI) with ID 23 is used for overflow interrupt requests.

Counter overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to 0xFFFF0000, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflow interrupt occurs.

--- Note ---

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

---

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any given PMNrx counter, when the value of PMOVSSET[x] is 1, the value of PMINTENSET[x] is 1, and one of the following is true:
  - EL2 is not implemented and the value of PMCR.E is 1.
  - EL2 is implemented, x is less than the value of HDCR.HPMN, and the value of PMCR.E is 1.
  - EL2 is implemented, x is greater than or equal to the value of HDCR.HPMN, and the value of HDCR.HPME is 1.
- The cycle counter, when the values of PMOVSSET[31], PMINTENSET[31], and PMCR.E are all 1.
The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMNx where x is greater than or equal to the value of HDCR.HPMN can be signaled from all modes and states but only if the value of HDCR.HPME is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to PMOVSCLR[x] to clear the overflow bit to 0.

**Pseudocode description of overflow interrupt requests**

See Chapter J1 *ARMv8 Pseudocode* for a pseudocode description of overflow interrupt requests. The AArch64.CheckForPMUOverflow() and AArch32.CheckForPMUOverflow() pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.
D6.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:
- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be Attributable either to the current Exception level alone, or to both the Exception level and the Security state of another PE with the same values for affinity level 1 and higher.

Note

- In an implementation containing multiple PEs, each PE is identified by a unique affinity value reported by MPIDR_EL1{Aff3, Aff2, Aff1, Aff0}, where the value of affinity level 0 is the most significant for determining the PE behavior, and the values of higher affinity levels are less significant. Affinity level 3 is only supported in AArch64 state.
- An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, thread is used to mean processing elements with different affinity level 0 values and the same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:
- Interaction with EL3 on page D6-2545.
- Event filtering on page D6-2547.
- Performance Monitors and Debug state on page D6-2549.

These sections are summarized by Table D6-1 for events Attributable to the processor, and Unattributable events.

Table D6-1 Counting events
D6.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

• Interaction with EL3.
• Interaction with EL2 on page D6-2546.

D6.5.1 Interaction with EL3

While counting events is never prohibited in Non-secure state, there are some restrictions on counting events in Secure state. From reset, counting events Attributable to Secure state is prohibited in Secure state. When executing in AArch32 state, software can set SDCR.SPME to 1 to permit event counting in Secure state. In AArch64 state, software can set MDCR_EL3.SPME to 1 to permit event counting in Secure state.

Note

This enables a Secure Monitor to permit profiling within Secure state without having to configure an IMPLEMENTATION DEFINED debug authentication interface.

The system can use the external authentication interface to override SPME.

If EL3 is not implemented, the behavior is as if the value of SDCR.SPME or MDCR_EL3.SPME is 1, as appropriate.

Counting Attributable events in Secure state is prohibited unless any one of the following is true:

• EL3 is not implemented.
• EL3 is implemented, is using AArch64, and the value of MDCR_EL3.SPME is 1.
• EL3 is implemented, is using AArch32, and the value of SDCR.SPME is 1.
• EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of SDER32_EL3.SUNIDEN is 1.
• In ARMv8.0 and ARMv8.1 implementations, EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Note

Software can read the Authentication Status register, DBGAUTHSTATUS, to determine the state of an IMPLEMENTATION DEFINED authentication interface.

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

The cycle counter, PMCCNTR, counts even when event counting is prohibited, unless PMCR.DP is set to 1 or the PE is in Debug state.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the SDER.SUNIDEN bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

Note

• Additional controls in PMCR, HDCR, PMCNTENSET, and PMCNTENCLR can also disable the event counters and the cycle counter.
• Controls in PMEVTYPE<n> and PMCCFILTR can also disable counting based on Exception level and Security state.
See `AArch64.CountEvents()` and `AArch32.CountEvents()` in Chapter J1 *ARMv8 Pseudocode* for more information. The `CountEvents()` functions return `TRUE` if PMN\(x\) counts events or the cycle counter counts cycles at the current Exception level and state. However, these functions do not completely describe the behavior for Unattributable events.

In AArch32 state, the Performance Monitors registers are Common registers, see *Classification of System registers* on page G5-5586.

The Performance Monitors are intended to be broadly accurate and statistically useful, see *Accuracy of the Performance Monitors* on page D6-2540. Some inaccuracy is permitted at the point of changing Security state, however. To avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

### Multithreaded implementations

If an implementation is multithreaded and the value of `PMEVTYPER<n>.MT == 1`, then the PE does not count an event that is Attributable to Secure state on another thread if counting events Attributable to Secure state is prohibited in Secure state on the PE that is counting the events.

**Example D6-1 The effect of having `PMEVTYPER<n>.MT == 1`**

If the value of `MDCR_EL3.SPME` is 0 on one thread, then it does not count events Attributable to Secure state on another thread, even if one or both of the following applies:

- This thread is in Non-secure state.
- `MDCR_EL3.SPME==1` on the other thread.

Otherwise:

- When the current configuration prohibits counting of events Attributable to Secure state in Secure state, it is implementation defined whether:
  - Counting events Attributable to Secure state on this PE in Non-secure state is permitted.
  - Counting Unattributable events related to other secure operations in the system is permitted.
- Otherwise, counting events in Non-secure state is permitted.

### D6.5.2 Interaction with EL2

When EL2 is implemented and enabled in the current Security state, software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the PMCR, so that it can fully virtualize the PMU identity registers, `PMCR.IMP` and `PMCR.IDCODE`.
- Reserve the highest-numbered counters for its own use by overriding the value of `PMCR.N` seen by the Guest OS. The PE does not permit a Guest OS to access the reserved counters.

HDCR controls Performance Monitors virtualization.

For more information, see:

- *Counter enables* on page D6-2550.
- *Counter access* on page D6-2551.
D6.6 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D6.6.1 Filtering by Exception level and PE state

In AArch64 state:

- For each event counter PMEVTYPER<\(n>\)_EL0 specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- PMCCFILTR_EL0 specifies the Exception levels in which the cycle counter counts.

In an implementation that supports multithreading:

- When the value of PMEVTYPER<\(n>_EL0.MT is 1, if an event is Attributable to another thread, then the specified filtering applies to the current Exception level and PE state of the thread to which the event is attributable, regardless of the Exception level and state of the counting thread.
- When the value of PMEVTYPER<\(n>_EL0.MT is 0, the event only counts events that are attributable to the counting thread, and the filtering applies to the Exception level and PE state of the counting state, see Example D6-2.

Example D6-2 Example of the effect of the PMEVTYPER<\(n>_EL0.MT control

If the value of PMEVTYPER<\(n>_EL0.U is 0 on the current thread, then it does not count events Attributable to EL0 on the other thread, even if this thread is not executing at EL0.

 Otherwise, for each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

In AArch32 state, the filtering controls are provided by the PMEVTYPER<\(n> and PMCCFILTR registers.

For more information, see the individual register descriptions.

D6.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- Exception-related events.
- Software increment events on page D6-2548.

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- EXC_TAKEN, Exception taken.
- EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return.
- CID_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
- TTBR_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to translation table base.
The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR after the return from the exception.

**Software increment events**

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any Speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening Context synchronization event must increment the event counter twice.

For more information, see SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.

**Pseudocode description of event filtering**

See AArch64.CountEvents() and AArch32.CountEvents() in Chapter J1 ARMv8 Pseudocode for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.
D6.7 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the value of $PMEVTYPER<\text{n}>$._EL0.MT is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is implementation defined whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in Filtering by Exception level and PE state on page D6-2547 apply for the current Security state in Debug state.
D6.8 Counter enables

Table D6-2 shows an implementation that does not include EL2, and where the PMCR.E bit is a global counter enable bit, and PMCNTENSET provides an enable bit for each counter.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
</tr>
</tbody>
</table>

If the implementation includes EL2, then in addition to the PMCR.E and PMCNTENSET enable bits:

- HDCR.HPME overrides the value of PMCR.E for counters configured for access in Hyp mode.
- HDCR.HPMN specifies the number of performance counters that the Guest OS can access. The minimum permitted value of HDCR.HPMN is 1, meaning there must be at least one counter that the Guest OS can access.

Table D6-3 shows the combined effect of all the counter enable controls.

<table>
<thead>
<tr>
<th>HDCR.HPME</th>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>x &lt; HDCR.HPMN</td>
<td>x ≥ HDCR.HPMN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0</td>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx disabled</td>
</tr>
<tr>
<td>0 1</td>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
</tr>
<tr>
<td>1 0</td>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
</tr>
<tr>
<td>1 1</td>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
</tr>
</tbody>
</table>

--- Note ---

- The effect of HDCR. {HPME, HPMN} on the counter enables applies at all Exception levels and in both Security states.
- The value returned for PMCR.N is not affected by HDCR.HPMN at:
  - EL3.
  - EL2.
  - Secure EL1, if ARMv8.4-SecEL2 is not implemented and enabled.
  - EL0, if ARMv8.4-SecEL2 is not implemented and enabled.

EL2 does not affect the enabling of PMCCNTR. Table D6-4 shows the PMCCNTR enables, for all implementations.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[31] == 0</th>
<th>PMCNTENSET[31] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR enabled</td>
</tr>
</tbody>
</table>
D6.9 Counter access

All implemented counters are accessible in EL3, Secure EL1 and EL2. If EL2 is implemented the hypervisor uses HDCR.HPMN to reserve an event counter, with the effect that software cannot access that counter and its associated state from Non-secure EL1 or from Non-secure EL0.

--- Note ---

This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers is subject to the access permissions described in Configurable instruction enables and disables, and trap controls on page D1-2208. In particular, accesses from EL0 might be UNDEFINED and accesses might be trapped to EL1 or EL2.

D6.9.1 PMNx event counters

For an implementation that includes EL2 and EL3, Table D6-5 shows how the values of the HDCR.HPMN field control the behavior of accesses to the PMNx event counter registers. In this table:

- **NS** The Effective value of SCR_EL3.NS.
- **EEL2** The Effective value of SCR_EL3.EEL2.

### Table D6-5 Result of PMNx event counter accesses

Where Table D6-5 shows no access:

- If PMSEL.R.SEL is $n$ then:
  - A direct read of PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
  - A direct write to PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
- A direct read of PMEVTPYTER<$n$> or PMEVCNTR<$n$> is CONSTRAINED UNPREDICTABLE.
- A direct write of PMEVTPYTER<$n$> or PMEVCNTR<$n$> is CONSTRAINED UNPREDICTABLE.
- For direct reads and direct writes, PMOVSCLR[$n$], PMOVSET[$n$], PMCNTENCLR[$n$], PMINTENSET[$n$], and PMINTENCLR[$n$] are RAZ/WI.
- Direct writes to PMSWINC[$n$] are ignored.
- A direct write of 1 to PMCR.P does not reset PMN.$n$.

For more information on the CONSTRAINED UNPREDICTABLE behavior of the Performance Monitor Extension, see:
- For AArch32, The Performance Monitors Extension on page K1-7201.
- For AArch64, The Performance Monitors Extension on page K1-7220.

--- Note ---

The value returned for PMCR.N is not affected by HDCR.HPMN at:

- EL3.
- EL2.
- Secure EL1, if ARMv8.4-SecEL2 is not implemented and enabled.
D6.9.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See Configurable instruction enables and disables, and trap controls on page D1-2208.
D6.10 PMU events and event numbers

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- Definitions.
- The PMU event number space and common events on page D6-2557.
- Common event numbers on page D6-2558.
- Cycle event counting on multithreaded implementations on page D6-2581.
- Meaningful ratios between common microarchitectural events on page D6-2582.
- Required events on page D6-2582.
- IMPLEMENTATION DEFINED event numbers on page D6-2583.

D6.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- Definition of terms.
- Levels of caches and TLBs on page D6-2556.
- Shared caches and buses on page D6-2556.

Definition of terms

Instruction architecturally executed

*Instruction architecturally executed* is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a *Simple sequential execution* of the program. Therefore an instruction that has been executed and retired is defined to be *architecturally executed*. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a *Simple sequential execution* of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A `NOP`.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, `CBZ`, instruction that does not branch.
- A Compare and Branch on Nonzero, `CBNZ`, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.

Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its Condition code check.

For events that count only the execution of instructions that update context state, such as writes to the CONTEXTIDR, if such an instruction is executed twice without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

Instruction architecturally executed, Condition code check pass

*Instruction architecturally executed, Condition code check pass* is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, `CBZ`, instruction that does not branch.
- A Compare and Branch on Nonzero, `CBNZ`, instruction that does not branch.
• A Test and Branch on Zero, TBZ, instruction that does not branch.
• A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
• A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for Instruction architecturally executed.

Instruction memory access
A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:
• Fetching instructions that are architecturally executed.
• The result of the execution of an instruction preload instruction, PLI.
• Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

Memory-read operations
A PE accesses memory through memory-read operations and Memory-write operations. A memory-read operation might be due to:
• The result of an architecturally executed memory-reading instructions.
• The result of a Speculatively executed memory-reading instructions.
• A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:
• Memory-read operations or Memory-write operations that miss in the cache
• The execution of a data preload instruction.
• The execution of an instruction preload instruction on a unified cache.
• The execution of a cache maintenance instruction.

Note
A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

Memory-write operations
Memory-write operations might be due to:
• The result of an architecturally executed memory-writing instructions.
• The result of a Speculatively executed memory-writing instructions.

Note
Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.
For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see Memory-read operations.
- The execution of a cache maintenance instruction.

**Note**

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

**Note**

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

**Microarchitectural operation**

It is permissible for an implementation of a PE to break down instructions into separate, smaller, operations. The use of Microarchitectural operations (micro-ops) is IMPLEMENTATION DEFINED.

**Slot**

An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an implementation specific point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

Each possible micro-op that can be executed at that point in a cycle is called a Slot. The maximum number of micro-ops that can be executed is defined by PMMIR.SLOTS.

**Speculatively executed**

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more micro-ops at any point in the execution pipeline. For the purpose of event counting, the micro-ops are counted. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. micro-ops might also be removed or merged in the execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of micro-ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed micro-op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch. Therefore, ARMv8-A defines these events as operation speculatively executed, where appropriate.
--- Note ---

The definition of *speculatively executed* does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDM instruction of six registers into six micro-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load micro-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event if the PC was one of the six registers in the LDM instruction.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

---

**Levels of caches and TLBs**

The mapping of different levels of cache or TLB to the PMU events is determined by the implementation. Although the CLIDR_EL1, or the AArch32 CLIDR, defines the implemented levels of cache, the architecture does provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

---

**Shared caches and buses**

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

---

**Example D6-3 First and second order effects of a cache miss in a multiple-PE implementation**

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.
D6.10 PMU events and event numbers

D6.10.2 The PMU event number space and common events

In ARMv8.0, the event number space is 10 bits. ARMv8.1 extends the event number space, and therefore the PMEVTYPER<El0.evCount field to 16 bits, and is allocated as Table D6-6 shows. For more information about the entries in the Allocation column see the text that follows this table:

The meaning of the entries in the Allocation column of Table D6-6 is as follows:

**Common architectural and microarchitectural events**

ARM defines the use of these event numbers. For more information see Common event numbers on page D6-2558.

**ARM-recommended common architectural and microarchitectural events**

The use of these event numbers is IMPLEMENTATION DEFINED. For more information see:

- IMPLEMENTATION DEFINED event numbers on page D6-2583.
- Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events.

**IMPLEMENTATION DEFINED event numbers**

For more information about the use of these event numbers see IMPLEMENTATION DEFINED event numbers on page D6-2583.
D6.10.3 Common event numbers

The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

• Be used for its assigned event.
• Not be used.

However, see Required events on page D6-2582.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

--- Note ---

ARM might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

---

Table D6-7 lists the PMU common architectural and microarchitectural event numbers in event number order. The entries in the Event mnemonic column link to the event description in Common architectural events on page D6-2562 or Common microarchitectural events on page D6-2566.

</table>
The supported common architectural and microarchitectural events are identified by:

- The PMCEID0_EL0 and PMCEID1_EL0 registers in AArch64 state.
- The PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers in AArch32 state.

ARM recommends that the value of 0 is used for the PMCEID0_EL0 or PMCEID1_EL0 bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

**Note**

- For example, if an implementation never generates the L1D_CACHE_ALLOCATE event, event 31, ARM recommends that PMCEID0_EL0[31] is RAZ.

- In an implementation that supports both Execution states, each bit in the AArch64 PMCEID0_EL0 and PMCEID1_EL0 registers corresponds to a single bit in the AArch32 PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers, and corresponding bits must have the same behavior.

However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding PMCEIDn_EL0 bit might be RAO.

Event numbers that Table D6-6 on page D6-2557 shows as allocated for common architectural and microarchitectural events that are not shown in Table D6-7 on page D6-2558 are reserved. Future revisions of this manual, or of the architecture, might assign these reserved values to additional common events. Events that do not require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

**Note**

- The requirement that an event that is implemented retrospectively does not require additional features in the PMU means that it must be possible to represent the event in the PMEVTYPER<n>_EL0.evtCount field. This means, for example, that an implementation with a 12-bit PMEVTYPER<n>_EL0.evtCount field can only implement events with event numbers 0x000-0xFFF.

- This means that, for example, an ARMv7 PMUv2 implementation, for which the evtCount field is 8 bits, can include support for any of the event numbers that Table D6-7 on page D6-2558 defines in the range 0x000-0xFFF.
Common architectural events

This section describes the use of the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a *Simple sequential execution* model.

The events corresponding to the common architectural event numbers are:

0x0000, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment

The counter increments on writes to the PMSWINC register.

If the PE performs two architecturally executed writes to the PMSWINC register without an intervening Context synchronization event, then the counter is incremented twice.

If PMEVTYPER<n>_EL0.evtCount is set to 0x000, then in AArch64 state, counts MSR writes to PMSWINC_EL0 with bit [n] set to 1.

If the value of PMEVTYPER<n>_EL0.MT is 1 then, in a multithreaded implementation, this counts writes by all PEs that have the same affinity at level 1 and above.

0x0006, LD_RETIRED, Instruction architecturally executed, Condition code check pass, load

The counter increments for every executed memory-reading instruction.

Note

This event 0x006 does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

0x0007, ST_RETIRED, Instruction architecturally executed, Condition code check pass, store

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

0x0008, INST_RETIRED, Instruction architecturally executed

The counter increments for every architecturally executed instruction.

0x0009, EXC_TAKEN, Exception taken

The counter increments for each exception taken. See *Exception-related events on page D6-2547.*

Note

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, *Exception entry on page D1-2170.*
- For exceptions taken to an Exception level using AArch32, *AArch32 state exception descriptions on page G1-5274.*

0x000A, EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return

The counter increments for each executed exception return instruction. See also *Exception-related events on page D6-2547.* The following sections define the counted instructions:

- For an exception return from an Exception level using AArch64, *Exception return on page D1-2179.*
- For an exception return from an Exception level using AArch32, *Exception return instructions on page G1-5261.*
However, is CONSTRAINED UNPREDICTABLE whether this event counts the execution of an exception return instruction if either:

- Execution of the instruction is, itself, CONSTRAINED UNPREDICTABLE.

  **Note**

  Examples of when an exception return instruction is CONSTRAINED UNPREDICTABLE are if the instruction is executed at EL0, or in AArch32 state in System mode.

- Execution of the instruction sets PSTATE.IL and does not generate an exception return.

  **Note**

  A particular consequence of this CONSTRAINED UNPREDICTABLE behavior is that an implementation that does not support AArch32 state at EL1 or higher does not have to treat AArch32 MOV PC, LR instructions, and related instructions, as exception return instructions.

---

0x000B, **CID_WRITE_RETIRED**, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR

The counter increments for every write to CONTEXTIDR. See *Exception-related events on page D6-2547.*

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

When ARMv8.1-VHE is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named register CONTEXTIDR_EL1, even when executing at EL2.
- Not incremented as a result of the retirement of an instruction accessing the named CONTEXTIDR_EL12.

  **Note**

  The event is defined by the name used to access the register. The counter does not count writes to the named register CONTEXTIDR_EL2.

---

0x000C, **PC_WRITE_RETIRED**, Instruction architecturally executed, Condition code check pass, software change of the PC

The counter increments for every software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMCE.

It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.

The counter does not increment for exceptions other than those explicitly identified in these lists.

  **Note**

  Conditional branches are only counted if the branch is taken.

---

0x000D, **BR_IMMED_RETIRED**, Instruction architecturally executed, immediate branch

The counter counts all immediate branch instructions that are architecturally executed.
In AArch32 state, the counter increments each time the PE executes one of the following instructions:

- \( \text{B\{<c>\} <label>} \).
- \( \text{BL\{<c>\} <label>} \).
- \( \text{BLX\{<c>\} <label>} \).
- \( \text{CBZ <Rn>, <label>} \).
- \( \text{CBNZ <label>} \).

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:

- \( \text{B <label>} \).
- \( \text{B.cond <label>} \).
- \( \text{BL <label>} \).
- \( \text{CBZ <Rn>, <label>} \).
- \( \text{CBNZ <Rn>, <label>} \).
- \( \text{TBZ <Rn>, <label>} \).
- \( \text{TBNZ <Rn>, <label>} \).

**Note**

Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

\( 0x000F \), \( \text{UNALIGNED_LDS_T_RETIRE} \), Instruction architecturally executed, Condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled. This event does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled. It is IMPLEMENTATION DEFINED whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

See \( \text{SP alignment checking} \) on page D1-2164 for more information.

See \( \text{Unaligned data access} \) on page E2-3580 for more information.
0x001C, TTBR_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR

The counter counts writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and TTBR0 and TTBR1 in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of TTBR0 and TTBR1. See Exception-related events on page D6-2547.

If the PE executes two writes to the same TTBR, without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to TTBR0_EL3.

If EL2 is implemented and using AArch64, the counter does not count writes to TTBR0_EL2 and to VTTBR_EL2.

If EL2 is implemented and using AArch32, the counter does not count writes to HTTBR and to VTTBR.

When ARMv8.1-VHE is implemented, the counter is:

• Incremented as a result of the retirement of an instruction accessing the named registers TTBR0_EL1 and TTBR1_EL1.
• Not incremented as a result of the retirement of an instruction accessing the named registers TTBR0_EL12 and TTBR1_EL12.

0x001E, CHAIN

For an odd-numbered counter, increments when an overflow occurs on the preceding even-numbered counter on the same PE. Even-numbered counters never increment as a result of this event. This means the CHAIN event links the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

_______ Note _________

• The CHAIN event means a system can provide \( N \) 32-bit counters, \( N/2 \) 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
• The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it is unaffected by the value of PMEVTYPER\(<n>_EL0.MT.

To filter the Exception levels and Security states in which the event is counted, software must:

• Program PMEVTYPER\(<n>_EL0 to count the event in the required conditions.
• Program PMEVTYPER\(<n+1>_EL0 to count the CHAIN event in all Exception levels and states.

This allows, (but does not require) hardware to ignore the filter settings for the CHAIN event and behave as if they are set to count in all Exception levels and states.

If software does not program the event in this way, the count becomes UNPREDICTABLE.

There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence, or employ reasonable heuristics, to avoid tearing. Similarly, if using CHAIN events, when disabling the counters software must take care that the result is not torn by the low counter overflowing at the same time as the counters are disabled Example D6-4 shows suitable sequences for disabling and enabling CHAIN counters.

Example D6-4 Usage examples for 64-bit counters

An example high-low-high read sequence for a 64-bit counter is:

```
MRS W2, PMEVCNTR1_EL0   ;; read high counter, must be odd-numbered
retry:
  ISB                    ;; force ordering
  MRS W0, PMEVCNTR0_EL0  ;; read low counter
  ;; must return the previous counter to PMEVCNTR1_EL0
  ISB                    ;; force ordering
```
MRS W1, PMEVCNTR1_EL0        ;; read high counter
CMP W1, W2
BNE retry                   ;; if the high counter has changed, then retry

When disabling a pair of counters that are paired by a CHAIN event, software must:
1. Disable the low counter, by setting PMEVCNTR<n>_<EL0>[n] to 1.
   Typically, software uses a read-modify-write sequence to update PMCNTENCLR_EL0.
2. Execute an ISB instruction, or perform another Context synchronization event.
3. Disable the high counter, by setting PMCNTENCLR_EL0[n+1] to 1, or setting PMCR_EL0.E to 0.

When enabling a pair of counters that are paired by a CHAIN event, software must:
1. Enable the high counter, by setting PMCNTENCLR_EL0[n+1] to 0 and, if necessary, setting PMCR_EL0.E to 1.
2. Execute an ISB instruction, or perform another Context synchronization event.
3. Enable the low counter by setting PMCNTENCLR_EL0[n] to 0.

When using 64-bit counters, the architecture does not define the latency between the first counter
overflowing and the second counter incrementing the CHAIN event. There is no requirement for
updates to occur synchronously, but software reading or enabling the counter pair using a
low-ISB-high sequence, as shown in Example D6-4 on page D6-2565, must not observe the low
counter incrementing and overflowing for the event and the high counter not incrementing for the
resulting CHAIN event. This means that the ISB executed after reading the low counter must ensure
the completion of the update of the high counter by the CHAIN event.

0x0021, BR_RETIRED, Instruction architecturally executed, branch
The counter counts all branches on the architecturally executed path that would incur cost if
mispredicted.
\[\begin{itemize}
  \item Counts all branch instructions, memory-reading and data-processing instructions that
        explicitly write to the PC, at retirement.
  \item Counts both taken and not-taken branches.
  \item It is implementation defined whether this includes each of:
        \begin{itemize}
          \item Unconditional direct branch instructions.
          \item Exception-generating instructions.
          \item Exception return instructions.
          \item Context synchronization instructions.
        \end{itemize}
\end{itemize}\]

0x8006, SVE_INST_RETIRED, Instruction architecturally executed, SVE
This event counts architecturally executed SVE instructions. It is IMPLEMENTATION DEFINED
whether this event counts non-SIMD SVE instructions.

Common microarchitectural events
This section describes the use of the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of
implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation
between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation
of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not
be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that
share it, ARM recommends that the resource implements its own event counters. An example of a resource that
might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency
port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions
relating to Level 1 caches generally assume the Level 1 cache is not shared.
The events corresponding to the common microarchitectural event numbers are:

0x0001, **L1I_CACHE_REFILL**, Level 1 instruction cache refill

The counter counts each access counted by L1I_CACHE that causes a demand refill of any of the Level 1 caches outside the Level 1 caches of this PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0002, **L1I_TLB_REFILL**, Attributable Level 1 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each Instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:
- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:
- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0003, **L1D_CACHE_REFILL**, Level 1 data cache refill

The counter counts each access counted by L1D_CACHE that causes a demand refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:
- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If ARMv8.4-PMU is not implemented, cache maintenance instructions.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.
0x0004, L1D_CACHE, Level 1 data cache access
The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 1 data or unified cache. If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

Each access to a cache line is counted including the multiple accesses of instructions, such as LD or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also Attributability on page D6-2544.

0x0005, L1D_TLB_REFILL, Attributable Level 1 data TLB refill
The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed
The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

0x0011, CPU_CYCLES, Cycle
The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a WFI or WFE instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by WFI and WFE instructions.

Note

Unlike PMCCNTR, this count is not affected by PMCR.DP, PMCR.D, or PMCR.C:

- The counter is not incremented in prohibited regions, so is not affected by PMCR.DP.
- The counter increments on every cycle, regardless of the setting of PMCR.D.
- The counter is reset when event counters are reset by PMCR.P, never by PMCR.C.

In a multithreaded implementation, CPU_CYCLES counts each cycle for the processor for which this PE thread was active and could issue an instruction. For more information, see Cycle event counting on multithreaded implementations on page D6-2581.

0x0012, BR_PRED, Predictable branch Speculatively executed
The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.
If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by BR_MIS_PRED.

If no program-flow prediction resources are implemented, this event is optional, but ARM recommends that BR_PRED counts all branches.

0x0013, MEM_ACCESS, Data memory access
The counter counts Memory-read operations and Memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:
• Instruction memory accesses, see Definition of terms on page D6-2553.
• Translation table walks.
• Write-back from any cache.
• Refilling of any cache.

If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

0x0014, L1I_CACHE, Attributable Level 1 instruction cache access
The counter counts Attributable instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

See also Attributability on page D6-2544.

0x0015, L1D_CACHE_WB, Attributable Level 1 data cache write-back
The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:
• A write-back that causes data to be written to a Level 2 cache or memory.
• A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
• Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back. Whether write-backs made as a result of cache maintenance instructions are counted is IMPLEMENTATION DEFINED.

The counter does not count:
• The invalidation of a cache line without any write-back to a Level 2 cache or memory.
• Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See Attributability on page D6-2544.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also Attributability on page D6-2544.
0x0016, **L2D_CACHE, Level 2 data cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 2 data or unified cache. If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also [Attributability](#) on page D6-2544.

0x0017, **L2D_CACHE_REFILL, Level 2 data cache refill**

The counter counts each access counted by L2D_CACHE that causes a refill of a demand refill of any of the Level 1 or Level 2 caches from outside the Level 1 and Level 2 caches of the PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
- Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
- Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count, as events on this PE:

- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If ARMv8.4-PMU is not implemented, cache maintenance instructions.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability](#) on page D6-2544.
- [Meaningful ratios between common microarchitectural events](#) on page D6-2582.

0x0018, **L2D_CACHE_WB, Attributable Level 2 data cache write-back**

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
- Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
• Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
• Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also Attributability on page D6-2544.

0x0019, BUS_ACCESS, Attributable Bus access

The counter counts Memory-read operations and Memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request. If the bus is shared, then an Unattributable bus access is not counted. If the bus is not shared, then the event is counted.

If the bus is shared, then only Attributable bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is implementation defined.

See also:
• Attributability on page D6-2544.
• Meaningful ratios between common microarchitectural events on page D6-2582.

0x001A, MEMORY_ERROR, Local memory error

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

0x001B, INST_SPEC, Operation Speculatively executed

The counter counts instructions that are Speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. The definition of Speculatively executed is IMPLEMENTATION DEFINED.

0x001D, BUS_CYCLES, Bus cycle

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

--- Note ---

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

---

See also *Meaningful ratios between common microarchitectural events on page D6-2582.*

0x001F, **L1D_CACHEALLOCATE,** Attributable Level 1 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:

- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also *Attributability on page D6-2544.*

0x0020, **L2D_CACHEALLOCATE,** Attributable Level 2 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back from a Level 1 to Level 2 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also *Attributability on page D6-2544.*

0x0022, **BR_MISPRED RETIRED,** Instruction architecturally executed, mispredicted branch

The counter counts all instructions counted by **BR RETIRED** that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

0x0023, **STALL_FRONTEND,** No operation issued due to the frontend

The counter counts every cycle counted by the CPU_CYCLES event on which no operation was issued because there are no operations available to issue for this PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. **STALL,** **STALL_FRONTEND,** and **STALL_BACKEND** events must count at the same point in the pipeline.

--- Note ---

- For a simplified pipeline model of Fetch → Decode → Issue → Execute → Retire, ARM recommends that the events are counted when instructions are dispatched from Decode to Issue.
- On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

For more information, see *Cycle event counting on multithreaded implementations on page D6-2581.*

0x0024, **STALL_BACKEND,** No operation issued due to the backend

The counter counts every cycle counted by the CPU_CYCLES event on which no operation was issued because either:

- The backend is unable to accept any of the operations available for issue for this PE.
- The backend is unable to accept any operations.

For example, the back end might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. **STALL,** **STALL_FRONTEND,** and **STALL_BACKEND** events must count at the same point in the pipeline.

See **STALL_FRONTEND** for more information.

For more information, see *Cycle event counting on multithreaded implementations on page D6-2581.*
0x0025, **L1D_TLB, Attributable Level 1 data or unified TLB access**

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB record is counted including the multiple accesses of instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also [Attributability](#) on page D6-2544.

0x0026, **L1I_TLB, Attributable Level 1 instruction TLB access**

The counter counts each Attributable Instruction memory access that causes a TLB access to at least the Level 1 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also [Attributability](#) on page D6-2544.

0x0027, **L2I_CACHE, Attributable Level 2 instruction cache access**

The counter counts Attributable instruction memory accesses that access at least the Level 2 instruction or unified cache. Each Attributable access to other Level 2 instruction memory structures, such as refill buffers, is also counted.

See also [Attributability](#) on page D6-2544.

0x0028, **L2I_CACHE_REFILL, Attributable Level 2 instruction cache refill**

The counter counts each access counted by L2I_CACHE that causes a demand refill of any of the Level 1 or 2 caches outside the Level 1 or 2 caches of this PE.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:

- [Attributability](#) on page D6-2544.
- [Meaningful ratios between common microarchitectural events](#) on page D6-2582.

0x0029, **L3D_CACHE_ALLOCATE, Attributable Level 3 data cache allocation without refill**

The counter increments on every Attributable write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back from a Level 2 to Level 3 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability](#) on page D6-2544.

0x002A, **L3D_CACHE_REFILL, Attributable Level 3 data cache refill**

The counter counts each access counted by L3D_CACHE which causes a demand refill of any of the Level 1, Level 2, or Level 3 caches from outside the Level 1, Level 2, and Level 3 caches.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count as events on this PE:

- A miss that does not cause a new refill but is satisfied by the refill of a previous miss, even if that previous refill is not complete at the time of the miss.
- A miss that does not generate a refill, such as a write through the cache.
- If ARMv8.4-PMU is not implemented, cache maintenance instructions.
If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.

See also:
• Attributability on page D6-2544.
• Meaningful ratios between common microarchitectural events on page D6-2582.

0x002B, L3D_CACHE, Attributable Level 3 data cache access

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 3 data or unified cache. If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

Each access to a cache line is counted including refills of and write-backs from the Level 1 or Level 2 data, instruction, or unified caches. Each access to other Level 3 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also Attributability on page D6-2544.

0x002C, L3D_CACHE_WB, Attributable Level 3 data cache write-back

The counter counts every write-back of data from the Level 3 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 3 cache to outside of the Level 1, Level 2, and Level 3 caches. For example, the counter counts the following cases:
• A write-back that causes data to be written to a Level 4 cache, or to memory.
• A write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:
• A transfer of data from the Level 3 cache to outside the Level 1, Level 2, and Level 3 caches made as a result of a coherency request.
• A write-back made as a result of a Cache maintenance instruction.

The counter does not count:
• The invalidation of a cache line without any write-back to a Level 4 cache or memory.
• Writes from the PE, Level 1, or Level 2 data or unified cache, that write through the Level 3 cache to outside of the Level 3 cache.
• Transfers of data from the Level 3 cache to a Level 1 or Level 2 cache, to satisfy a Level 1 or Level 2 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then Unattributable write-back events are not counted. If the cache is not shared, then Unattributable write-back events are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also Attributability on page D6-2544.

0x002D, L2D_TLB_REFILL, Attributable Level 2 data TLB refill

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB refill of at least the Level 2 data or unified TLB. It counts each Attributable read or Attributable write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:
• A refill results in a Translation fault.
• A refill is not allocated in the TLB.
The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- *Attributability* on page D6-2544.
- *Meaningful ratios between common microarchitectural events* on page D6-2582.

0x002E, L2I_TLB_REFILL, Attributable Level 2 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 2 instruction TLB. This includes each Attributable Instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- *Attributability* on page D6-2544.
- *Meaningful ratios between common microarchitectural events* on page D6-2582.

0x002F, L2D_TLB, Attributable Level 2 data or unified TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB record is counted, including the multiple accesses of instructions such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also *Attributability* on page D6-2544.

0x0030, L2I_TLB, Attributable Level 2 instruction TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 instruction TLB.

The counter does not count TLB maintenance instructions.

See also *Attributability* on page D6-2544.

0x0031, REMOTE_ACCESS, Access to another socket in a multi-socket system

The counter counts each Attributable memory read operation or memory write operation that causes an access to another socket in a multi-socket system.

It is IMPLEMENTATION DEFINED whether an access that causes a snoop into another socket but does not return data from or pass data to the remote socket is counted.

See also *Attributability* on page D6-2544.

0x0032, LL_CACHE, Last Level cache access

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Last Level data or unified cache. If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

See also *Attributability* on page D6-2544.
0x0033, LL_CACHE_MISS, Last Level cache miss
The Counter counts each Attributable Memory-read operation or Memory-write operation that causes a cache access to at least the Last Level data or unified cache, but is not completed by the Last Level cache. That is, either of the following:
- A memory read operation that does not return data from the Last Level cache.
- A memory write operation that does not update the Last Level cache.
The counter does not count operations that are completed by a cache above the Last Level cache.
If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0034, DTLB_WALK, Access to data TLB causes a translation table walk
The counter counts each Attributable memory read or memory write operation that causes a refill of a data or unified TLB involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.
The counter does not count TLB maintenance instructions.
See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0035, ITLB_WALK, Access to instruction TLB that causes a translation table walk
The counter counts each Attributable Instruction memory access that causes a refill of an instruction TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.
The counter does not count TLB maintenance instructions.
See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0036, LL_CACHE_RD, Attributable Last level cache memory read
As LL_CACHE, but counts only memory read accesses.
If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted by this event.
See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.

0x0037, LL_CACHE_MISS_RD, Last level cache miss, read
As LL_CACHE_MISS, but counts only memory read operations.
If ARMv8.4-PMU is not implemented, the counter does not count cache maintenance instructions. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
See also:
- Attributability on page D6-2544.
- Meaningful ratios between common microarchitectural events on page D6-2582.
0x0038, **REMOTE_ACCESS_RD**, Access to another socket in a multi-socket system, read

As **REMOTE_ACCESS**, but counts only memory read operations.

See also:
- **Attributability** on page D6-2544.
- **Meaningful ratios between common microarchitectural events** on page D6-2582.

0x0039, **L1D_CACHE_LMISS_RD**, Level 1 data cache long-latency read miss

The counter counts each memory read access counted by **L1D_CACHE** that incurs additional latency because it returns data from outside the Level 1 data or unified cache of this PE.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. It is **IMPLEMENTATION DEFINED** whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 1 data or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 1 data or unified cache.

This counter does not count:
- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 1 caches that the access looks up in that results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data and unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by **L1D_CACHE** might have a significant performance impact due to additional latency for the address.

See also **Attributability** on page D6-2544.

0x003A, **OP_RETIRED**, Micro-operation architecturally executed

The counter counts each operation counted by **OP_SPEC** that would be executed in a **Simple sequential execution** of the program.

0x003B, **OP_SPEC**, Micro-operation Speculatively executed

The counter counts the number of operations executed by the PE, including those that are executed speculatively and which would not be executed in a **Simple sequential execution** of the program.

0x003C, **STALL**, No operation sent for execution

The counter counts every Attributable cycle on which no Attributable instruction or operation was sent for execution on this PE.

If the implementation is multi-threaded:
- When **PMEVTYPER<\(n\>_EL0.MT = 0\(\emptyset\)**, the counter counts cycles for which only instructions or operations Attributable to other PEs are sent for execution when this PE is eligible to execute instructions or operations on that cycle. The counter does not count cycles when this PE of the multi-threaded operation is not eligible to execute instructions or operations.
- When **PMEVTYPER<\(n\>_EL0.MT = 0\(1\)**, the counter counts all cycles when no instructions or operations for any PE of the multi-threaded operation are sent for execution.

The division between frontend and backend is **IMPLEMENTATION DEFINED**. **STALL**, **STALL_FRONTEND**, and **STALL_BACKEND** events must count at the same point in the pipeline. For more information, see **STALL_FRONTEND**.

See also:
- **Attributability** on page D6-2544.
• Meaningful ratios between common microarchitectural events on page D6-2582.

0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend

Counts each Slot counted by STALL_SLOT where no Attributable instruction or operation was sent for execution because the backend is unable to accept one of:
  • The instruction operation available for the PE on the Slot.
  • Any operations on the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. STALL_SLOT, STALL_SLOT_FRONTEND, and STALL_SLOT_BACKEND events must count at the same point in the pipeline. The maximum value that STALL_SLOT_FRONTEND and STALL_SLOT_BACKEND events can count in a single-cycle is IMPLEMENTATION DEFINED. For more information, see STALL_SLOT.

See also Attributability on page D6-2544.

0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend

Counts each Slot counted by STALL_SLOT where no Attributable instruction or operation was sent for execution because there was no Attributable instruction or operation available to issue from the PE from the frontend for the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. STALL_SLOT, STALL_SLOT_FRONTEND, and STALL_SLOT_BACKEND events must count at the same point in the pipeline. The maximum value that STALL_SLOT_FRONTEND and STALL_SLOT_BACKEND events can count in a single-cycle is implementation defined. For more information, see STALL_SLOT.

— Note —

ARM recommends that STALL_SLOT_FRONTEND counts instructions that have been decoded and, if applicable, split into micro-operations.

See also Attributability on page D6-2544.

0x003F, STALL_SLOT, No operation sent for execution on a Slot

The counter counts on each Attributable cycle the number of instruction or operation Slots that were not occupied by an instruction or operation Attributable to the PE.

If the implementation is multi-threaded:
  • When PMEVTYPER<n>_EL0.MT = 0b0, the counter counts instruction or operation Slots for which those Slots are occupied by instructions or operations Attributable to other PEs of the multi-threaded implementation only when the PE was eligible to execute instruction or operations in that cycle. The counter does not count any instruction or operation Slots on cycles when this PE was not eligible to execute instructions or operations.
  • When PMEVTYPER<n>_EL0.MT = 0b1, for every cycle the counter counts all instruction or operation Slots not occupied by any instruction or operation for any PE of the multi-threaded implementation.

If ARMv8.4-PMU is implemented:
  • If STALL_SLOT is not implemented, it is IMPLEMENTATION DEFINED whether the PMMIR System registers are implemented.
  • If STALL SLOT is implemented, then the PMMIR System registers are implemented.

See also Attributability on page D6-2544.

0x0040, L1D_CACHE_RD, Level 1 data cache memory read

As L1D_CACHE, but counts only memory read accesses.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

See also:
  • Attributability on page D6-2544.
• Meaningful ratios between common microarchitectural events on page D6-2582.

0x4000, SAMPLE_POP, Sample Population
The counter increments for each operation that might be sampled, whether or not the operation was sampled. Operations that are executed at an Exception level or Security state in which the Statistical Profiling Extension is disabled are not counted.

0x4001, SAMPLE_FEED, Sample Taken
The counter increments each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the previous sample. Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x4002, SAMPLE_FILTRATE, Sample taken and not removed by filtering
The counter increments each time that a completed sample record is checked against the filters and not removed. Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event, are counted.

0x4003, SAMPLE_COLLISION, Sample collided with a previous sample
The counter increments for each sample record that is taken when the previous sampled operation has not completed generating its sample record.

0x4004, CNT_CYCLES, Constant frequency cycles
This event is defined identically to CNT_CYCLES in the AMUv1 architecture.

0x4005, STALL_BACKEND_MEM, Memory stall cycles
This event is defined identically to STALL_BACKEND_MEM in the AMUv1 architecture.

0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency read miss
The counter counts each access counted by L1I_CACHE that incurs additional latency because it returns instructions from outside the Level 1 instruction cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 1 instruction cache and might have a significant performance impact due to the additional latency, compared to the latency of an access that hits in the Level 1 instruction cache.

This counter does not count:
• Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 1 caches that the access looks up in that results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data and unified cache.
• A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by L1I_CACHE might have a significant performance impact due to additional latency for the address.

0x4009, L2D_CACHE_LMISS_RD, Level 2 data cache long-latency read miss
The counter counts each memory read access counted by L2D_CACHE that incurs additional latency because it returns data from outside the Level 2 data or unified cache of this PE.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
The event indicates to software that the access missed in the Level 2 data or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 2 data or unified cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 2 caches that the access looks up in that results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data and unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by L2D_CACHE might have a significant performance impact due to additional latency for the address.

See also Attributability on page D6-2544.

0x400A, L2I_CACHE_LMISS, Level 2 instruction cache long-latency read miss

The counter counts each access counted by L2I_CACHE that incurs additional latency because it returns instructions from outside the Level 2 instruction cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 2 instruction cache and might have a significant performance impact due to the additional latency, compared to the latency of an access that hits in the Level 2 instruction cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 2 caches that the access looks up in that results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data and unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by L2I_CACHE might have a significant performance impact due to additional latency for the address.

0x400B, L3D_CACHE_LMISS_RD, Level 3 data cache long-latency read miss

The counter counts each memory read access counted by L3D_CACHE that incurs additional latency because it returns data from outside the Level 3 data or unified cache of this PE.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

The event indicates to software that the access missed in the Level 3 data cache or unified cache and might have a significant performance impact compared to the latency of an access that hits in the Level 3 data or unified cache.

This counter does not count:

- Access where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared against a miss in all Level 3 caches that the access looks up in that results in an access being made to a Level 4 cache or elsewhere beyond the Level 3 data and unified cache. This might be counted as a Level 2 cache miss.
A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency nor to track the access to determine whether the additional latency had a performance impact. An implementation can extend the definition of this event with additional scenarios where a memory read access counted by L3D_CACHE might have a significant performance impact due to additional latency for the address.

See also Attribution on page D6-2544.

0x8006, SVE_INST_SPEC, Speculatively executed SVE instruction

This event counts speculatively executed operations due to SVE instructions. It is IMPLEMENTATION DEFINED whether this event counts non-SIMD SVE instructions.

D6.10.4 Cycle event counting on multithreaded implementations

For most events, the event is only counted when it is attributable to the counting PE or thread, see Attribution on page D6-2544.

Multithreaded implementations can have various forms, some examples of these are:

- Simultaneous Multithreading (SMT), where every PE thread is active on every cycle.
- Fine-grained Multithreading (FGMT), also known as a Barrel processor, where one PE thread is active on each cycle, and this changes regularly.
- Switch on Event Multithreading (SoEMT), also known as Coarse-grained Multithreading (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

When the PMEVTPER<n>_EL0.MT bit is set to 0, the CPU_CYCLES event only counts cycles on which the thread was active. For the example multithreaded implementations, this means that:

- For an SMT implementation, the CPU_CYCLES event counts every cycle.
- For a particular FGMT implementation, that alternates between two threads on each cycle, the CPU_CYCLES event counts every other cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the CPU_CYCLES event does not count cycles, as the PE thread is not active.

If the PMEVTPER<n>_EL0.MT bit is set to 1, the processor counts each cycle, and can only count a maximum of one cycle each cycle.

In addition, the STALL_FRONTEND and STALL_BACKEND events only count cycles that are counted by the CPU_CYCLES event, and so have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as STALL_BACKEND cycles.

If the PMEVTPER<n>_EL0.MT bit is set to 1, the PE only counts cycles on which no operation is issued from any thread.

Note

The PMCCNTR register counts every processor cycle.
### D6.10.5 Meaningful ratios between common microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. Table D6-8 lists the highlighted ratios.

### D6.10.6 Required events

PMUv3 requires that an implementation includes the following common events:

- 0x0000, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.
- 0x0003, L1D_CACHE_REFILL, Level 1 data cache refill.

#### Note

Event 0x0003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0004, L1D_CACHE, Level 1 data cache access.

#### Note

Event 0x0004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed.

#### Note

Event 0x0010 is only required if the implementation includes program-flow prediction. However, ARM strongly recommends that the event is implemented as described in Common microarchitectural events on page D6-2566.

- 0x0011, CPU_CYCLES, Cycle.
- 0x0012, BR_PRED, Predictable branch Speculatively executed.
Note

Event 0x0012 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in Common microarchitectural events on page D6-2566.

- At least one of:
  - 0x0008, INST_RETIRED, Instruction architecturally executed.
  - 0x0018, INST_SPEC, Operation Speculatively executed.

Note

ARM strongly recommends that event 0x008 is implemented.

- When ARMv8.1-PMU is implemented:
  - 0x0023, STALL_FRONTEND, No operation issued due to the frontend.
  - 0x0024, STALL_BACKEND, No operation issued due to the backend.
- When SVE is implemented:
  - 0x8002, SVE_INST_RETIRED, SVE instruction architecturally retired.
  - 0x8006, SVE_INST_SPEC, SVE instruction speculatively executed.
- When the Statistical Profiling Extension is implemented:
  - 0x4000, SAMPLE_POP, Sample Population.
  - 0x4001, SAMPLE_FEED, Sample Taken.
  - 0x4002, SAMPLE_FILTRATE, Sample Filtered.
  - 0x4003, SAMPLE_COLLISION, Sample Collision.
- When ARMv8.4-PMU is implemented:
  - 0x003C, STALL, No operation sent for execution.
  - 0x0039, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss.
  - 0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss.
  - 0x0040, L1D_CACHE_RD, Level 1 data cache read.

When any of the following common events are implemented, all three of them are implemented:
- 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend,
- 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend.
- 0x003F, STALL_SLOT, No operation sent for execution on a Slot.

ARM strongly recommends that the following events are implemented:
- BR_RETIRED.
- BR_MIS_PRED_RETIRED.
- STALL_SLOT.
- STALL_SLOT_BACKEND.
- STALL_SLOT_FRONTEND.
- OP_SPEC.
- OP_RETIRED.

### D6.10.7 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:
- Increment only once for each event.
- Count the duration for which an event occurs.

ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.
ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the STALL_FRONTEND and STALL_SLOT_FRONTEND events to count holes in instruction availability.
- Separating each of the STALL_BACKEND and STALL_SLOT_BACKEND events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE. {A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The range of possible IMPLEMENTATION DEFINED event numbers is described in The PMU event number space and common events on page D6-2557. Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events lists the ARM recommended standardized numbering scheme for these events.
D6.11 Performance Monitors Extension registers

Further information on the Performance Monitors Extension Registers can be found in the following sections:

- Table K13-2 on page K13-7396 lists the Performance Monitors register names for AArch32 and AArch64 states.
- Performance monitors registers on page K13-7415 summarizes the Performance Monitors Extension registers in AArch64 state.
- Performance monitors registers on page K13-7437 summarizes the Performance Monitors Extension registers in AArch32 state.
D6 The Performance Monitors Extension

D6.11 Performance Monitors Extension registers
This chapter describes the ARMv8 implementation of version 1 of the Activity Monitor Unit (AMU) architecture, AMUv1, an optional non-invasive component. It contains the following sections:

- *About the Activity Monitors Extension* on page D7-2588.
- *Properties and behaviour of the activity monitors* on page D7-2589.
- *AMU events and event numbers* on page D7-2591.

---

**Note**

Table K13-3 on page K13-7397 disambiguates the general register references used in this chapter.
D7.1 About the Activity Monitors Extension

The Activity Monitors Extension is an optional extension to the ARMv8.4 architecture.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, AMUv1, and interfaces to the registers defined by AMUv1, the Activity Monitors registers.

Version 1 of the Activity Monitors architecture implements:

- A counter group of four architected 64-bit event counters. The events counted by the architected event counter are fixed and architecturally defined.

  __________ Note __________

  The Activity Monitors architecture provides space for up to 16 architected event counters. Future versions of the Activity Monitors architecture may use this space to implement additional architected event counters.

  __________

- A counter group of up to 16 auxiliary 64-bit event counters. The event counted for each auxiliary event counter may be fixed or programmable, and whether it is fixed or programmable is IMPLEMENTATION DEFINED. When the event counted by an auxiliary event counter is fixed, this event is IMPLEMENTATION DEFINED.

- Controls for enabling and disabling counters.

- When the event counted by an auxiliary event counter is programmable, controls for assigning an event to the counter.

- Controls that determine whether the activity monitor counters continue to count while the PE is halted in Debug state.

The read-only registers AMCFGR and AMCGCR provide information about features supported by the Activity Monitors Extension, the number of counter groups implemented, the total number of counters implemented, the number of counters implemented within each group, and the size of the counters.

The Activity Monitors Extension provides:

- A mandatory System register interface to the Activity Monitors registers, for both AArch64 and AArch32 states.

  __Base system registers on page K13-7421__ lists the AArch64 Activity Monitors registers, and __Base system registers on page K13-7442__ lists the AArch32 Activity Monitors registers. __Table K13-3 on page K13-7397__ shows the relationship between the AArch64 and the AArch32 Activity Monitors register.

- Controls that allow software to enable or disable access by software running at lower Exception levels to the Activity Monitors registers.

- An optional external interface providing read-only memory-mapped access to the Activity Monitors registers.

  __Alphabetical index of memory-mapped registers on page K13-7446__ lists the Activity Monitors memory-mapped registers. For more information on the recommended external interface, see __Chapter I4 Recommended External Interface to the Activity Monitors__. 
D7.2 Properties and behaviour of the activity monitors

D7.2.1 Basic characteristics of the activity monitor event counters

Every activity monitor event counter is a 64-bit wrapping counter. When an activity monitor event counter wraps, the counter overflows.

**Note**
The Activity Monitor architecture does not provide support for overflow status indication or interrupts.

The state of the authentication signals do not affect counting.

Any change in clock frequency, including when a WFI and WFE instruction stops the clock, can affect any counter.

D7.2.2 Counter configuration and controls

For each architected event counter AMEVCNTR0<n>, there is a corresponding event type register AMEVTYPE0<n> which provides information on the event counted by that counter. The event type registers AMEVTYPE0<n> are read-only.

For each auxiliary event counter AMEVCNTR1<n> , there is a corresponding event type register AMEVTYPE1<n> which provides information on the event counted by that counter. When the event counted by an auxiliary event counter is fixed, the corresponding event type register AMEVTYPE1<n> is read-only. When the event counted by an auxiliary event counter is programmable, the corresponding event type register AMEVTYPE1<n> is read/write.

For each counter group, there is a pair of separate controls to enable and disable the counters in that counter group. AMCNTENCLR0 and AMCNTENSET0 are used to disable and enable the architected event counters. AMCNTENCLR1 and AMCNTENSET1 are used to disable and enable the auxiliary event counters.

While the PE is halted in Debug state, AMCR.HDBG controls whether activity monitor counting is halted.

AMUSERENR.EN controls access from EL0 to the Activity Monitor Extension System registers. CPTER_EL2.TAM and HCPTR.TAM control access from EL0 and EL1 to the Activity Monitor Extension System registers.

**Note**
These controls obey the priority order described in Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191 and Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5243.

AMUSERENR.EN is configurable at EL1, EL2, and EL3. All other controls, as well as the value of the counters, are configurable only at the highest implemented Exception level.

D7.2.3 Power and reset domains

The power domain of the activity monitoring unit is IMPLEMENTATION DEFINED.

The reset domain of the activity monitoring unit is IMPLEMENTATION DEFINED.

When a Cold reset of the power domain of the activity monitoring unit occurs, the activity monitoring unit is reset and the counters are reset to zero. When the PE is not in reset, the activity monitoring unit is available.
D7.4 Accuracy and non-invasive behaviour

The activity monitors are a non-invasive component which must provide broadly accurate and statistically useful count information.

The implementation of an architecturally required event might create a conflict between the requirement to be non-invasive and the requirement to present an accurate value of the count under normal operating conditions. An implementation might provide an IMPLEMENTATION DEFINED control that disables accurate count of the event to restore performance and document the impact on performance of accurate counting. The expectations for non-invasive behaviour and the degree of inaccuracy of the activity monitors are otherwise as described for the Performance Monitors architecture.

Note

For information on the expectations for non-invasive behaviour and the degree of inaccuracy of the Performance Monitors, see Non-invasive behavior on page D6-2540 and A reasonable degree of inaccuracy on page D6-2540.
D7.3  **AMU events and event numbers**

The Activity Monitors architecture uses the event number space defined by the Performance Monitors architecture to identify events.

The Activity Monitors architecture defines additional events and adds them to the event number space defined by the Performance Monitors architecture for common events.

When a common event is available to both the Performance Monitors architecture and the Activity Monitors architecture within one implementation, both architectures use the same event number.

D7.3.1  **Architected event counters**

Version 1 of the Activity Monitors architecture, AMUv1, requires four events to be counted by the architected activity monitor event counters.

The events required to be counted are:

- **0x0011, CPU_CYCLES, Processor frequency cycles**
  This event is defined identically to CPU_CYCLES in the PMUv3 architecture.
  When the PE is in WFI or WFE, this counter does not increment. When in a multithreaded implementation, regardless of which PE is currently active, this counter continues to count for all PEs not in WFI or WFE.
  This event is counted by AMEVCNTR0<n>, where n is 0.

- **0x4004, CNT_CYCLES, Constant frequency cycles**
  The constant frequency cycles counter increments at a constant frequency equal to the rate of increment of the System counter, CNTPCT_EL0.
  When the PE is in WFI or WFE, this counter does not increment. When in a multithreaded implementation, regardless of which PE is currently active, this counter continues to count for all PEs not in WFI or WFE.
  This event is counted by AMEVCNTR0<n>, where n is 1.

- **0x0008, INST_RETIRED, Instructions retired**
  This event is defined identically to INST_RETIRED in the PMUv3 architecture.
  This event is counted by AMEVCNTR0<n>, where n is 2.

- **0x4005, STALL_BACKEND_MEM, Memory stall cycles**
  The counter counts cycles in which the PE is unable to dispatch instructions from the frontend to the backend of the PE due to a backend stall caused by a miss in the last level of cache within the PE clock domain.
  This event is counted by AMEVCNTR0<n>, where n is 3.

D7.3.2  **Auxiliary event counters**

Auxiliary event counters can count events defined by the Performance Monitors architecture and IMPLEMENTATION DEFINED events defined specifically for activity monitoring.

Arm strongly recommends that implementations do not re-use an IMPLEMENTATION DEFINED event number for different hardware events across the Performance Monitors architecture and the Activity Monitors architecture.
The Activity Monitors Extension
D7.3 AMU events and event numbers
Chapter D8
The Statistical Profiling Extension

This chapter describes the Statistical Profiling Extension. It contains the following sections:

- About the Statistical Profiling Extension on page D8-2594.
- Defining the sample population on page D8-2596.
- Controlling when an operation is sampled on page D8-2598.
- Enabling profiling on page D8-2601.
- Filtering sample records on page D8-2602.
- The profiling data on page D8-2604.
- The Profiling Buffer on page D8-2609.
- Profiling Buffer management on page D8-2613.
- Synchronization and Statistical Profiling on page D8-2617.
D8.1 **About the Statistical Profiling Extension**

Statistical profiling is a four stage process.

1. An operation is chosen from a sample population, at a programmable interval that might have some random, or pseudorandom, perturbation.
2. A trace of the sampled operation is taken. This includes the PC, events, timings, and data addresses, related to the sampled operation. This is the profiling operation.
3. Before a sample record is created, it is possible to filter out potential sample records generated by the profiling operation by reference to, any or all of the following:
   a. The type of operation.
   b. The Exception level.
   c. Event and latency.
4. A sample record is created that contains the traced information. Sample records that meet the criteria of the filter are written to and stored in a memory buffer. These sample records can be processed by software when the memory buffer is full.

D8.1.1 **Non-invasive behavior**

Statistical Profiling is a non-invasive debug operation:

- While profiling is enabled, the operation and performance of the processing element (PE) must not be significantly impacted between sampled operations, that is, other than for writing out sample records and processing Profiling Buffer management interrupts.
- The performance of the sampled operation and the performance of the PE in general must not be significantly impacted. The sample records are not written to memory until after the sampled operation has completed. However, this does not apply when the user selects a collection of physical addresses for data access operations. In this case, the impact is IMPLEMENTATION DEFINED.
- The profiling operation to write sample records must not be excessively impactful on the performance of the sampled operation or the performance of the PE generally.

D8.1.2 **PMU extensions**

If the Statistical Profiling and Performance Monitoring Extensions are implemented, then the following PMU events must be implemented:

- SAMPLE_POP.
- SAMPLE_FEED.
- SAMPLE_FILTRATE.
- SAMPLE_COLLISION.

--- Note ---

These events are discoverable through a read of PMCEID0_EL0[35:32].

D8.1.3 **Multithreaded implementations**

In a multithreaded implementation:

- Statistical Profiling is implemented per-thread.
- The sample interval counter counts only operations for the thread that is being profiled.
- Latency and other cycle counters count each cycle for the PE for which the thread was active and could issue an operation.

The architecture does not define features for inter-thread profiling and does not support sharing the Profiling Buffer between threads.
Note

An implementation is described as multithreaded when the lowest level of affinity consists of logical processors that are implemented using a multi-threading type approach. That is, the performance of processors at the lowest affinity level is very interdependent. On such an implementation, the value of MPIDR_EL1.MT, when read at the highest implemented Exception level, is 1.
D8.2 Defining the sample population

All samples are taken from a population of operations. The population is dynamic rather than static. That is, if a program executes the same operation multiple times (for example, because of loops and subroutines) then that operation appears multiple times in the population.

The operations are an implementation defined choice between:

- Architecture instructions.
- Implementation defined microarchitectural operations (micro-ops).

**Architecture instruction** means a single instruction that is defined by the ARMv8 instruction set architecture in AArch64 state.

An architecture instruction might create one or more micro-ops at any point in the execution pipeline. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the execution stream, so an architecture instruction might create no micro-ops for an instruction.

Any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted. In some implementations, the relationship between architecture instructions and micro-ops might vary over time.

---

**Note**
Sampling from architecture instructions does not require that the instruction is architecturally executed.

---

D8.2.1 Operations that might be excluded from the sample population

It is implementation defined whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations (specifically micro-ops) that do not relate to any architecture instruction.
- Operations that generate non-architectural exceptions.

If the operation is not part of the sample population, the operation does not cause the sample interval counter to decrement, is not counted by the SAMPLE_POP event and therefore is never sampled.

If the operation is part of the sample population, the operation causes the sample interval counter to decrement, is counted by the SAMPLE_POP event, and might be sampled and counted by the SAMPLE_FEED event.

---

D8.2.2 Misspeculation and non-architectural operations

It is implementation defined whether the sample record for a sampled misspecified operation or a sampled operation generating a non-architectural exception is written to the Profiling Buffer:

- If a sample record of a misspecified operation or an operation generating a non-architectural exception is written to the Profiling Buffer, then neither event 0 (generated exception) nor event 1 (architecturally retired) are set in the record Events packet.
- If a sample record of a misspecified operation or an operation generating a non-architectural exception is not captured into the Profiling Buffer, then no event packets are output and the sample is not counted by the SAMPLE_FILTRATE event.

---

**Note**
It is implementation defined whether such operations can be sampled. See Operations that might be excluded from the sample population.

---

If such an operation is not part of the sample population

The operation does not cause the sample counter to decrement, is not counted by the SAMPLE_POP event, and hence is never sampled.
If such an operation is part of the sample population

The operation causes the sample counter to decrement, is counted by the SAMPLE_POP event, and might be sampled and counted by the SAMPLE_FEED event.

It is IMPLEMENTATION DEFINED whether the sample record for such an operation, if sampled, is captured in the Profiling Buffer:

- If such a sample record is captured in the Profiling Buffer then some information for the operation might not be present. However, the Events packet and either the End packet or the Timestamp packet is always output. Neither event 0 (generated exception) nor event 1 (architecturally retired) will be set in the Events packet.
- If such a sample record is not captured into the Profiling Buffer then no packets are output and the sample is not counted by the SAMPLE_FILTRATE event.

If the sample record for an operation on a misspeculated path is captured into the Profiling Buffer, then the record must not contain information that cannot be accessed by privileged software of the owning Exception level.

--- Note ---

If the Owning Exception level passes this data to less privileged software for processing, it can set PMSFCR_EL1.FE to 1 and PMSEVFR_EL1[1] to 1 to prevent speculative instructions from being recorded in the Profiling Buffer.
D8.3 Controlling when an operation is sampled

The sample interval counter, PMSICR_EL1.COUNT controls when an operation is selected for sampling. In some implementations, a secondary sample interval counter, PMSICR_EL1.ECOUNT, is also used.

The following sections describe the operation of the sample interval counters.

Details of the random or pseudorandom number generator used when PMSIRR_EL1.RND is set to 1 are IMPLEMENTATION DEFINED. See Generating random numbers for sampling.

D8.3.1 Operation sampling

A sample operation is as follows:

1. A sampling interval is written to PMSICR_EL1.COUNT by software. The interval is measured in operations.
2. The sample interval counter is decremented by hardware for each operation when sampling is enabled.
3. When the sample interval counter reaches zero, then:
   a. If random perturbation is enabled, the PE continues to count for a random number of further operations while sampling is enabled.
   b. An operation is chosen for profiling.

   **Note**

   The choice of operation around the sampling point is arbitrary. The chosen operation might be the operation for which the sample interval counter reached 0, or the next operation. The choice must be applied consistently so as not to introduce sampling bias.

4. The sample interval counter is reloaded and the process loops to step 2. It is IMPLEMENTATION DEFINED whether the sample interval counter is reloaded before step 3.a) or at step 3.b). That is, before or after counting the random number of further operations.
5. The chosen operation is marked as the sampled operation. The PE collects information about the sampled operation as it executes by a profiling operation.
6. When the sampled operation is completed, the sample record is created.

D8.3.2 Generating random numbers for sampling

The random number generator is IMPLEMENTATION DEFINED. Implementations might use a pseudorandom number. The random number generator must be reset into a useable state. An implementation might include IMPLEMENTATION DEFINED registers to further configure the random number generator.

It is IMPLEMENTATION DEFINED whether the PE adds the random number to the sample interval counter prior to counting down the interval, or after the counter reaches zero and the counter has been reloaded.

D8.3.3 Initializing the one or more sample interval counters

When the PE moves from a state where profiling is disabled to a state where profiling is enabled:

- If PMSICR_EL1 is nonzero, then sampling restarts from the current values in PMSICR_EL1.
- If PMSICR_EL1 is zero, then it is loaded with an initial value. The behavior depends on PMSIRR_EL1.RND and an IMPLEMENTATION DEFINED choice discoverable by a read of PMSIDR_EL1.ERnd.
- If PMSIRR_EL1.RND is 0:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to 0x00.
- If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range 0x00 to 0xFF.
- If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 1:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range 0x00 to 0xFF.
• If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0:
  — PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  — PMSICR_EL1.COUNT[7:0] is set to 0x00.

D8.3.4 Behavior of the sample interval counter while profiling is enabled

While profiling is enabled, the counters control when an operation is selected for sampling. The behavior depends on PMSIRR_EL1.RND and an IMPLEMENTATION DEFINED choice discoverable in PMSIDR_EL1.ERnd.

If PMSIRR_EL1.RND is cleared to 0:

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

• A member of the sampling population is selected for sampling.
• The counter is set as follows:
  — PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  — PMSICR_EL1.COUNT[7:0] is set to 0x00.

  Note  
  Because the counter counts down to zero, when PMSIRR_EL1.RND is cleared to 0 the interval between operations being selected for sampling is (INTERVAL×256+1).

If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

• A member of the sampling population is selected for sampling.
• The counter is set as follows:
  — PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  — PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range 0x00 to 0xFF.

  Note
  When PMSIRR_EL1.RND is set to 0 and PMSIDR_EL1.ERnd is 1, the mean interval between operations being selected for sampling is (INTERVAL×256+128), if the random number generator is uniform.

If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 1

While nonzero, the primary sample interval counter decrements by 1 for each member of the sample population. When the primary counter reaches zero:

• The primary sample interval counter is reloaded.
• The secondary sample interval counter, PMSICR_EL1.ECOUNT, is set to a random or pseudorandom value in the range 0x00 to 0xFF.

While the secondary sample interval counter is nonzero, the secondary sample interval counter decrements by 1 for each member of the sample population. The primary sample interval counter also continues to decrement because it is also nonzero.

When the secondary sample interval counter reaches zero, an operation is selected for sampling.

  Note
  When PMSIRR_EL1.RND is set to 1 and PMSIDR_EL1.ERnd is 1, the mean interval between operations being selected for sampling is (INTERVAL×256+1), if the random number generator is uniform.
D8.3.5 Behavior of the sample interval counter while profiling is disabled

When profiling is disabled:
• No operations are selected for sampling.
• No sample records are collected.
• The sample interval counters retain their values and do not decrement.

D8.3.6 Where operations are sampled

The exact point in the sampled lifespan of operations at which operations are chosen for profiling is IMPLEMENTATION DEFINED.

Note
ARM recommends that the point at which operations are sampled is linked to the definition of the Performance Monitoring Extension (PMU) STALL_FRONTEND and STALL_BACKEND events, so that sampling records information for STALL_BACKEND stalls.

D8.3.7 Sample collisions

The maximum number of sampled operations that a PE can support simultaneously is IMPLEMENTATION DEFINED. If the maximum number of simultaneous sampled operations has been reached at the point when a new operation must be sampled, the new sample is said to have collided with a previous sampled operation.

The PE records the fact that a sampled operation has collided with another sampled operation. Software can also count the number of collisions and gauge the impact of the collisions.

On a sample collision:
• The PMU event SAMPLE_COLLISION is generated.
• PMBSR_EL1.COLL is set to 1.
• The new operation is not sampled.

Following a context synchronization event an indirect write to PMBSR_EL1.COLL is guaranteed to be visible to instructions in program order after the sampled operation that collided. There is no guarantee of visibility without a context synchronization event. For more information see Synchronization and Statistical Profiling on page D8-2617.

Note
This means that following a context synchronization event PMBSR_EL1.COLL will not change on entry to a state where profiling is disabled.
D8.4 Enabling profiling

Profiling is disabled if the Profiling Buffer is disabled, including when:

- PMBLIMITR_EL1.E is cleared to 0 or PMBSR_EL1.S is set to 1.
- Executing at a higher Exception level than the Profiling Buffer owning Exception level.
- Executing in the Security state that is not the Security state of the owning Exception level.
- The PE is in Debug state.

Note

The owning Exception level is controlled by MDCR_EL3.NSPB and MDCR_EL2.E2PB.

PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} enable sampling by Exception level:

- In a guest operating system or Secure state, PMSCR_EL1.E1SPE enables profiling at EL1 and PMSCR_EL1.E0SPE at EL0.
- In a hypervisor or host operating system, PMSCR_EL2.E2SPE enables profiling at EL2 and PMSCR_EL2.E0HSPE at EL0.
- Sampling is always disabled at EL3.

Table D8-1 defines the valid combinations of the Effective values of PMBSR_EL1.S, PMBLIMITR_EL1.E, SCR_EL3.NS, SCR_EL3.EEL2, MDCR_EL3.NSPB, MDCR_EL2.E2PB, and HCR_EL2.TGE that define when sampling is enabled.

In Table D8-1:

D Disabled.

E2SPE Enabled if PMSCR_EL2.E2SPE == 1, disabled otherwise.

E1SPE Enabled if PMSCR_EL1.E1SPE == 1, disabled otherwise.

E0HSPE Enabled if PMSCR_EL2.E0HSPE == 1, disabled otherwise.

E0SPE Enabled if PMSCR_EL1.E0SPE == 1, disabled otherwise.

This is described in the pseudocode functions `ProfilingBufferEnabled()` and `CheckStatisticalProfilingAccess()`.

</table>
D8.5 Filtering sample records

PMSFCR_EL1.FT enables filtering by operation type. When enabled PMSFCR_EL1.{ST, LD, B} define the collected types:

- ST enables collection of store sampled operations, including all atomic operations.
- LD enables collection of load sampled operations, including atomic operations that return a value to a register.
- B enables collection of branch sampled operations, including direct and indirect branches and exception returns.

--- Note ---
When micro-op sampling is implemented, filtering is based on the micro-op type.

Table D8-2 summarizes the controls for filtering by operation type. In this table:

- Load Atomic refers to atomic operations which return a value to a general-purpose register. Other atomic operations are classed as Store.
- D indicates that the operation is discarded.
- C indicates that the operation is collected.

PMSFCR_EL1.FE enables filtering by a set of events that are defined by PMSEVFR_EL1. When enabled, only sampled operations with all the events in the filter set are recorded and written to the Profiling Buffer.

PMSFCR_EL1.FL enables filtering by total latency. PMSLATFR_EL1.MINLAT defines the minimum latency. When enabled, only sampled operations with a total latency greater than or equal to the minimum latency are recorded and written to the Profiling Buffer.

These controls combine together as a logical AND.

--- Example D8-1 Collection of sampled operations ---

If PMSFCR_EL1.FE is set to 1, PMSFCR_EL1.FT is set to 1, and PMSFCR_EL1.FL is set to 1, then only sampled operations that meet all of the following criteria are recorded and written to the Profiling Buffer:

- The sampled operation is one of the selected operation types.
• The operation has all of the events in the filter set.
• The total latency is equal to or greater than the minimum latency.

This is described in the pseudocode function `CollectRecord()`. 
D8.6 The profiling data

Unless otherwise stated all sample records that are generated by a profiling operation contain:

- A timestamp, if enabled. This is one of:
  - CNTPCT_EL0.
  - CNTVCT_EL0.

It is IMPLEMENTATION DEFINED how this timestamp relates to the sampled operation. It might be the time when the sampled operation was taken or any later time during the lifetime of the sampled operation, that is, up to the time when the sampled operation is completed.

If the Generic Timer system counter is disabled and timestamps are enabled, then it is IMPLEMENTATION DEFINED whether:
- The Statistical Profiling Extension behaves as if timestamps are disabled.
- The timestamp that is collected in the sample record is UNKNOWN.

--- Note

This behavior describes when CNTEN.EN is cleared to 0. This behavior does not apply when the Generic Timer system counter is enabled but not accessible at the current Exception level.

- The context, if enabled, which is one or more of:
  - CONTEXTIDR_EL1.
  - CONTEXTIDR_EL2.
  - The Exception level.
  - The Security state.

- Information about whether the sampled operation generated an exception:
  - The target address for an exception generating operation is not collected.

- Information about whether the sampled operation completed execution.

If the sampled operation completes execution and does not generate an exception, the sample record also contains:

- The PC virtual address for the sampled operation.
- Information about whether the sampled operation is a branch, a load, a load atomic, a store, or other.
- Information about whether the sampled operation is conditional, conditional select, or not.
- The total latency, a cycle count of the lifetime of the sampled operation. For more information see Lifespan of a sampled operation on page D8-2607.
- The issue latency, a cycle count from the start of the sampled operation up to the point when at least one part of the sampled operation starts executing. A sampled operation might be delayed, for example, because the input operands were not available.

If the sampled operation does not complete execution or generates an exception it is UNPREDICTABLE whether the record contains all or any of this information and the other information about the operation listed in this section and the following subsections. For information on exceptions being taken in sampled operations see Exceptions on page D8-2607.

The architecture defines a set of additional data that is collected in the sample record for each sampled operation. This is described in the following subsections, and comprises:

- Events.
- Cycle counters. Cycle count values as described in this architecture, which, for a particular implementation, are fixed with an IMPLEMENTATION DEFINED value, might be omitted from the sample record.
- Addresses.

In addition, the architecture permits IMPLEMENTATION DEFINED events, counters, and addresses to be collected.

D8.6.1 Additional information for each profiled branch or exception return

For a completed branch or exception return sampled operation, the profiling operation must record:

- The sampled operation type as an unconditional branch or a conditional branch. Sampled exception returns are treated as unconditional branches by the Statistical Profiling Extension.
• The target virtual address of the branch. The target virtual address includes the Exception level and Security state of the target.

—— Note ———
If the sampled operation is an illegal exception return, it is IMPLEMENTATION DEFINED whether the context information recorded in the target virtual address is the actual target context, or the target context that is described by the SPSR.

• If the PE implements branch prediction, whether the branch was correctly predicted or mispredicted.
• Whether the branch was taken or not taken.
• Whether the branch was direct or indirect.

—— Note ———
A sampled operation that generates an exception is not treated as a branch.

D8.6.2 Additional information for each profiled memory access operation

For a completed load, store, or atomic sampled operation that does not generate an exception, the profiling operation must record:
• The data virtual and, if enabled, physical addresses being accessed.
  — If the applicable Top Byte Ignore (TBI) bit is set to one, the virtual address includes any top-byte tag.
  — The physical address is the address the PE accesses in the physical address space, and so includes the Secure Address Space Identifier.
• The sampled operation type, which includes:
  — Whether the sampled operation is a load, store, or atomic.
  — Whether the sampled operation is Load-Exclusive, Store-Exclusive or Load-acquire, Store-release.
  — Whether the sampled operation accesses the general-purpose or SIMD&FP registers.
• The translation latency. This is defined as an IMPLEMENTATION DEFINED choice between:
  — The count of cycles for which at least a part of a load or store operation is waiting for the MMU to complete an address translation, and no part of the operation is accessing memory.
  — The count of cycles for which at least a part of a load or store operation is waiting for the MMU to complete an address translation.
• Whether the sampled operation accessed the Level 1 data cache and resulted in a hit.
• Whether the sampled operation accessed the data TLB and resulted in a hit.
• An optional, IMPLEMENTATION DEFINED, record of whether the sampled operation accessed Last Level data cache and resulted in a hit.
• An optional, IMPLEMENTATION DEFINED, record of whether the sampled operation accessed another socket in a multi-socket system.
• An optional, IMPLEMENTATION DEFINED, indicator of the data source for a load.

For each of the Last level cache and another socket indicators, it is IMPLEMENTATION DEFINED whether this information is present only for load accesses, only for store accesses, for neither, or for both.

—— Note ———
A store might be marked as not accessing a cache or another socket because it completed before doing so. For example, the write was held in a write buffer. This behavior is IMPLEMENTATION DEFINED, and such events must be interpreted with care.

———
If architecture instructions are sampled, for a sampled load/store operation that is not single-copy atomic, the data addresses are the lowest address that is accessed by the sampled operation regardless of whether architecture instructions are sampled or not.

Otherwise the information is for the micro-op that is sampled.
Example D8-2 Sampling of micro-ops

If an architectural load instruction is split into an address generation micro-op and a load micro-op, then when generating the sample record and filtering based on operation type:

- If the address generation micro-op is sampled, the sampled operation is treated as other.
- If the load micro-op is sampled, the sampled operation is treated as a load.

D8.6.3 Additional information for each profiled conditional instruction (including conditional branches)

For a completed conditional branch, conditional select, conditional move, or conditional increment sampled operation, the profiling operation must record:

- That the sampled operation was conditional.
- Whether the condition passed or failed.

If a conditional instruction fails its condition code test, it is IMPLEMENTATION DEFINED whether any of the information for the sampled operation that is generated by executing the sampled operation is recorded. Any value that is recorded and is the result of executing the sampled operation is UNKNOWN.

Example D8-3 Conditional branches

A conditional branch operation fails its condition code test. It is IMPLEMENTATION DEFINED whether the sample record contains a branch target Address packet. If the sample record contains a branch target Address packet, the value in the packet is UNKNOWN.

D8.6.4 Additional information for other operations

For cache maintenance operations by virtual address, cache prefetch, or address translation instructions, the profiling operation:

- Captures an IMPLEMENTATION DEFINED subset of the information captured for a load instruction.
- Treats the operation type as other when generating the sample record and filtering based on operation type.

See Filtering sample records on page D8-2602 and Operation Type packet.

D8.6.5 Controlling the data that is collected

Certain data in sample records is only collected if permitted by one or both of EL1 and EL2. This is to restrict exposure of data to a lower Exception level or to Non-secure state.

CONTEXTIDR_EL1 is collected only if PMSCR_EL1.CX is set to 1 and all of the following are true:

- The PE is executing at EL1 or EL0.
- The PE is executing in Secure state and ARMv8.4-SecEL2 is not implemented, or the Effective value of HCR_EL2.TGE is 0.

CONTEXTIDR_EL2 is collected only if the Effective value of PMSCR_EL2.CX is 1 and EL2 is implemented and enabled for the current Security state.

This is described in the pseudocode functions CollectContextIDR1() and CollectContextIDR2().

Timestamps are collected only if one of the following is true:

- PMSCR_EL1.TS is set to 1 and the Profiling Buffer is owned by EL1.
- PMSCR_EL2.TS is set to 1 and the Profiling Buffer is owned by EL2.

The timestamp is a choice between:

- Physical time, which is defined by the value of CNTPCT_EL0.
• Virtual time, as defined by the value of CNTVCT_EL0. That is, the physical time minus the virtual offset, CNTVOFF_EL2. However, the virtual offset is treated as zero if a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

Physical time is collected if any of the following is true:
• PMSCR_EL1.PCT is set to 1 and the Profiling Buffer is owned by Secure EL1 and EL2 is disabled or is not implemented.
• PMSCR_EL2.PCT is set to 1 and the Profiling Buffer is owned by Secure or Non-secure EL2.
• PMSCR_EL1.PCT is set to 1 and PMSCR_EL2.PCT is set to 1 and the Profiling Buffer is owned by Non-secure EL1, or the Profiling Buffer is owned by Secure EL1 and Secure EL2 is enabled.

Virtual time is collected otherwise. If EL2 is not implemented, PMSCR_EL1.PCT is RES1. This is described by the pseudocode function CollectTimeStamp().

Physical data addresses are collected only if one of the following is true:
• PMSCR_EL1.PA is set to 1 and the Profiling Buffer is owned by Secure EL1 and EL2 is disabled or is not implemented.
• PMSCR_EL2.PA is set to 1 and the Profiling Buffer is owned by Secure or Non-secure EL2.
• PMSCR_EL1.PA is set to 1 and PMSCR_EL2.PA is set to 1 and either the Profiling Buffer is owned by Non-secure EL1, or the Profiling Buffer is owned by Secure EL1 and Secure EL2 is enabled.

If EL2 is not implemented or is disabled for the current Security state, the PE behaves as if PMSCR_EL2.PA is set to 1, other than for a direct read of the register.

Enabling collection of the physical data addresses has an IMPLEMENTATION DEFINED impact on the sampled operation. This is described by the pseudocode function CollectPhysicalAddress().

D8.6.6 Lifespan of a sampled operation

The sampled lifespan of an operation:
• Starts with the decoded architectural instruction or micro-op is dispatched for issue.
• Completes when one of:
  — The instruction or micro-op is committed to the architectural state of the PE (including completion by generating a synchronous exception).
  — The speculative instruction or micro-op is discarded because of misspeculation. For more information see Misspeculation and non-architectural operations on page D8-2596.
  — The instruction or micro-op is replayed, on some microarchitectures. For more information see Non-architectural exceptions on page D8-2608.

D8.6.7 Exceptions

All sample records written to the Profiling Buffer contain the Events packet and either the End packet or the Timestamp packet.

If the sampled operation generates an exception, it is UNPREDICTABLE whether the sample record contains any other information.

Where a sampled operation generates an exception and the type of exception means that a particular item is not computed by the sampled operation, that information is not collected by the profiling operation. For more information see Synchronization and Statistical Profiling on page D8-2617.

Example D8-4 Translation Faults

If a sampled operation generates a Translation Fault, the physical address for the sampled operation was not generated by the MMU and cannot be recorded.
Non-architectural exceptions

An implementation might include exceptions that are not architectural exceptions. That is, in executing an operation, the PE performs some exceptional behavior that does not take an exception as defined by the architecture. These non-architectural exceptions are usually not visible to software.

The use on non-architectural exceptions are IMPLEMENTATION DEFINED.

If a sampled operations generates a non-architectural exception, the sample might include handling of the non-architectural exception. If the sample does not include handling of the non-architectural exception, then the sampled operation does not complete because of the non-architectural exception and it is recorded using E[1] == 0 (operation did not retire) in the Events packet. Bit E[0] (operation generated an exception) might be used to indicate the operation did not complete because of the non-architectural exception.
D8.7 The Profiling Buffer

The profile data is collected in a memory Profiling Buffer. The Profiling Buffer is defined by:

- PMBPTR_EL1, the current write pointer.
- PMBLIMITR_EL1, the write limit pointer.

The Profiling Buffer starts at the current write pointer and extends to the current limit pointer minus one. The write limit pointer must be aligned to the smallest implemented translation granule size. The alignment of the current write pointer is IMPLEMENTATION DEFINED.

PMBLIMITR_EL1 and PMBPTR_EL1 are virtual addresses in the stage 1 translation regime of the owning Exception level. This is called the owning translation regime.

Note

The translation of virtual addresses to physical addresses is identical to that for any other virtual address in the owning Exception level. For example, PMBPTR_EL1[63:56] are ignored by address translation if the respective TBI bit is set to 1.

D8.7.1 Restrictions on the current write pointer

This section describes the software rules on setting the current write pointer, PMBPTR_EL1. If these rules are not followed, the value returned for a direct read of PMBPTR_EL1 is UNKNOWN, the behavior is UNPREDICTABLE, and the PE might do any of the following at any point after profiling is enabled:

- Write sample records to any writeable address in memory that is writable at the owning Exception level.
- Generate a Profiling Buffer management event, with or without indicating data loss, for one of the following reasons:
  - The Profiling Buffer is full.
  - Any MMU Fault.

When profiling becomes enabled, all the following must be true:

- The current write pointer must be at least one sample record below the write limit pointer. That is:
  \[ \text{UInt}(\text{PMBPTR_EL1.PTR}) \leq \text{UInt}(\text{PMBLIMITR_EL1.LIMIT} : \text{Zeros}(12)) - 2^{\text{PMSIDR_EL1.MaxSize}}. \]
- PMBPTR_EL1.PTR[63:56] must equal PMBLIMITR_EL1.LIMIT[63:56].

When the Profiling Buffer is first configured, PMBPTR_EL1.PTR must be aligned to PMBIDR_EL1.Align. That is, if PMBIDR_EL1.Align is nonzero, PMBPTR_EL1.PTR [\text{UInt}(\text{PMBIDR_EL1.Align})-1:0] must be all zeros.

However, the current write pointer can usually be restored to the saved write pointer value it had when profiling was disabled, providing a PSB CSYNC and a context synchronization event were executed before reading PMBPTR_EL1:

- If no Profiling Buffer management event was signaled then profiling can be restarted from the saved write pointer. In this case, the saved write pointer points within one sample record of the write limit pointer.
- If a Profiling Buffer management event was signaled then:
  - If PMBSR_EL1.S is restored to 1, then profiling is not being enabled, and there are no constraints on the value written to PMBPTR_EL1.
  - If PMBSR_EL1.S is restored to 0, and the Profiling Buffer management event was caused by an MMU fault, profiling can be restarted from the saved write pointer; if PMBSR_EL1.{EA, DL} did not also indicate an external abort or data loss, and the saved write pointer is at least one sample record below the write limit pointer.

Note

If a signaled MMU fault has not been corrected, the Statistical Profiling Extension generates a new MMU fault Profiling Buffer management event when it next tries to write a sample record.

- If PMBSR_EL1.S is restored to 0, and the Profiling Buffer management event was caused by a buffer full event, the Profiling Buffer can be extended and profiling restarted from the saved write pointer; if PMBSR_EL1.{EA, DL} did not also indicate an external abort or data loss and the saved write pointer is at least one sample record below the extended write limit pointer.
The current write pointer must not be restored from the saved write pointer following a Profiling Buffer management event if PMBSR_EL1.DL was set to 1.

The saved write pointer might not be aligned to 2^PMBIDR_EL1.Align and might point to within one sample record of the write limit pointer.

For more information see Synchronization and Statistical Profiling on page D8-2617.

D8.7.2 The owning Exception level

The owning Exception level is:

- Non-secure EL1, if all of the following are true:
  - Either EL3 is not implemented and the PE is executing in Non-secure state, or MDCR_EL3.NSPB is set to either 0b10 or 0b11.
  - Either EL2 is not implemented and the PE is executing in Non-secure state, or MDCR_EL2.E2PB is set to either 0b10 or 0b11.
- Non-secure EL2, if all of the following are true:
  - EL2 is implemented.
  - Either EL3 is not implemented or MDCR_EL3.NSPB is set to either 0b10 or 0b11.
  - MDCR_EL2.E2PB is set to 0b00.
- Secure EL1, if any of the following are true:
  - EL3 is not implemented and the PE is executing in Secure state.
  - MDCR_EL3.NSPB is set to either 0b00 or 0b01.
- Secure EL2, if all of the following are true:
  - EL2 is implemented and SCR_EL3.EEL2 is 1.
  - HCR_EL2.{TGE,E2H} are set to {1,1}.
  - SCR_EL3.NS is 0.
  - Either EL3 is not implemented and the PE is executing in Non-secure state, or MDCR_EL3.NSPB is set to either 0b00 or 0b01.

When the owning Exception level is Non-secure EL1

The Profiling Buffer addresses are in the Non-secure EL1&0 translation regime using the current ASID from TTBRx_EL1. This is a two-stage translation using the current VMID if EL2 is implemented and HCR_EL2.VM is set to 1.

If EL3 is implemented, then the Profiling Buffer is disabled in Secure state.

If EL2 is implemented, then profiling is disabled at EL2 and at Non-secure EL0 when HCR_EL2.TGE is set to 1.

When the owning Exception level is Non-secure EL2

The Profiling Buffer addresses are in the EL2 translation regime. If both HCR_EL2.E2H is set to 1 and HCR_EL2.TGE is set to 1, this is an EL2&0 translation regime using the current EL2&0 translation regime ASID from TTBRx_EL2.

If EL3 is implemented, then the Profiling Buffer is disabled in Secure state.

--- Note ---

If either HCR_EL2.E2H is cleared to 0 or HCR_EL2.TGE is cleared to 0, and the PE is executing at EL1 or EL0, the EL2 translation regime is not the current stage 1 translation regime because the current stage 1 translation regime is EL1&0.

---

When the owning Exception level is Secure EL1

The Profiling Buffer addresses are in the Secure EL1&0 translation regime using the current ASID from TTBRx_EL1.
If EL3 is implemented, then the buffer is disabled in Non-secure state.

The Profiling Buffer is disabled if any of the following are true:

- `SCR_EL3.NS` indicates the other Security state to the owning Exception level.
- The owning Exception level is using AArch32 state.
- `PMBLIMITR_EL1.E` is cleared to 0.

### When the owning Exception level is Secure EL2

The Profiling Buffer addresses are in the Secure EL1&0 translation regime using the current ASID from TTBRx_EL1.

If EL3 is implemented, then the buffer is disabled in Non-secure state.

The Profiling Buffer is disabled if any of the following are true:

- `SCR_EL3.NS` or `SCR_EL3.EEL2` indicates the other Security state to the owning Exception level.
- The owning Exception level is using AArch32 state.
- `PMBLIMITR_EL1.E` is cleared to 0.

Table D8-3 summarizes the owning translation regime.

---

### D8.7.3 Memory access types and coherency

The Statistical Profiling Extension acts as a separate observer in the system and is subject to the rules regarding coherency.

The memory type that is used for a write by the Statistical Profiling Extension to the Profiling Buffer is taken from the translation table entries for the virtual address being written to. That is:

- The writes are treated as coming from an observer that is coherent with all observers in the Shareability domain that is defined by the translation tables.
- There is no requirement to manage coherency for observers in the same Shareability domain but coherency for other observers in the system might require explicit management.

For more information see *Synchronization and Statistical Profiling on page D8-2617*. 
D8.7.4 TLB operations

Translations might be cached in a TLB. TLB maintenance operations (including TLB maintenance operations that are broadcast from other PEs) operate on these cached translations.

Any TLB maintenance operation followed by a DSB (including an operation broadcast from another PE and a following DSB on that other PE):

• Does not complete until all sample records previously translated using an invalidated translation have been written to the Profiling Buffer.

• Any remaining sample records are guaranteed not to use an invalidated translation.

For such operations, the DSB must apply to both loads and stores. Although the Statistical Profiling Extension acts as another observer in the system, for determining the Shareability domain of this DSB or TLB maintenance operation, the writes of sample records are treated as coming from the PE that is being profiled.

Note

Completion of the DSB does not guarantee that all buffered profiling data has written out. See Synchronization and Statistical Profiling on page D8-2617.

D8.7.5 Effect on the exclusive monitors

If an operation between Load-Exclusive and Store-Exclusive instructions is sampled, then the Store-Exclusive must be guaranteed not to fail, even though the sample record is written to an unrelated address.
D8.8 Profiling Buffer management

A Profiling Buffer management event occurs:

- On a fault, see Faults and watchpoints on page D8-2614.
- On an external abort, see External aborts on page D8-2615.
- When the Profiling Buffer fills, see Buffer full event on page D8-2614.

On a Profiling Buffer management event:

- The service bit, PMBSR_EL1.S, is set to 1.
- The data loss bit, PMBSR_EL1.DL, is set as described in the event description.
- The Profiling Buffer management interrupt request signal, PMBIRQ, is asserted:
  - PMBIRQ is a level-sensitive interrupt request driven by PMBSR_EL1.S. This means that a direct write that sets PMBSR_EL1.S to 1 causes the interrupt to be asserted, and PMBIRQ remains asserted until software clears PMBSR_EL1.S to 0.
  - If a Generic Interrupt Controller (GIC) is implemented, PMBIRQ must be configured as a Private Peripheral Interrupt (PPI) in a multiprocessor system. PMBIRQ is signaled by the PE that implements the Statistical Profiling Extension.

Note
A standard PPI number is allocated by the ARM®Server Base System Architecture (SBSA).

- Additional syndrome for the event is written to PMBSR_EL1.MSS. Unless otherwise stated in the event description, other PMBSR_EL1 fields are unchanged.

While PMBSR_EL1.S is set to 1:

- The buffer is disabled and profiling is disabled.
- All remaining buffered sample records are discarded.
- The values in PMBPTR_EL1 are retained and PMSICR_EL1 does not decrement.

Buffer full events and MMU fault Profiling Buffer management events are reported synchronously.

Note
Reported synchronously means that profiling is disabled before the SPE samples further operations. The interrupt exception resulting from asserting the Profiling Buffer interrupt request is an asynchronous exception.

It is IMPLEMENTATION DEFINED whether external aborts are reported to the Statistical Profiling Extension synchronously or asynchronously. If external aborts are reported as asynchronous:

- The external abort might not be received until after a first Profiling Buffer management event has set PMBSR_EL1.S to 1.
- Writes to the buffer might generate a second Profiling Buffer management event after the external abort has set PMBSR_EL1.S to 1.

The architecture does not require that a sample record is written sequentially by the Statistical Profiling Extension, only that:

- The Statistical Profiling Extension never writes past the PMBLIMITR_EL1 limit pointer.
- On a Profiling Buffer management interrupt, PMBSR_EL1.DL indicates whether PMBPTR_EL1 points to the first byte after the last complete sample record.
- On an MMU fault or synchronous external abort, PMBPTR_EL1 serves as a Fault Address Register.

Note
This means that it must not be assumed that:
  - There is ever any valid data beyond the current PMBPTR_EL1 write pointer.
  - The PE has not written a valid sample record between the current PMBPTR_EL1 write pointer and the PMBLIMITR_EL1 limit pointer.
  - If PMBSR_EL1.DL is set to 1 on a Profiling Buffer management interrupt, that there is any valid data between the end of the last complete sample record and the current PMBPTR_EL1 write pointer.
Any valid data has been written to the Profiling Buffer if an external abort is reported asynchronously to the Statistical Profiling Extension.

- The last complete sample record must end at most \(2^{(\text{PMSIDR\_EL1.MaxSize})}\) bytes below \(\text{PMBPTR\_EL1}\).

## D8.8.1 Prioritization of Profiling Buffer management events

Where multiple synchronous Profiling Buffer management events occur on writing a sample record, the PE prioritizes them as follows (from highest to lowest priority):

1. Synchronous fault.
2. Synchronous external abort.
3. Buffer full event.

Asynchronous external aborts are not prioritized with respect to other events.

--- Note ---

Prioritization of Profiling Buffer management interrupt requests is managed by the interrupt controller. Profiling Buffer management events are prioritized internally by the PE.

## D8.8.2 Buffer full event

If, after writing a sample record, there is not sufficient space in the Profiling Buffer for a sample record of the size indicated by \(\text{PMSIDR\_EL1.MaxSize}\) and \(\text{PMBSR\_EL1.S}\) is 0, a Profiling Buffer management event is generated:

- \(\text{PMBSR\_EL1.\text{EC}}\) is set to \(0b000000\), other buffer management event.
- The BSC field of \(\text{PMBSR\_EL1.MSS}\) is set as follows:
  - \(\text{PMBSR\_EL1.BSC}\) is set to \(0b000001\), buffer filled.
- \(\text{PMBPTR\_EL1}\) is set to the first byte after the last complete sample record. \(\text{PMBSR\_EL1.DL}\) is unchanged.
- The other \(\text{PMBSR\_EL1}\) fields are unchanged.

That is, the Profiling Buffer management event is generated when the PE writes past the write limit pointer minus \(2^{(\text{PMSIDR\_EL1.MaxSize})}\). The Statistical Profiling Extension never writes beyond the write limit pointer.

For more information see [Restrictions on the current write pointer](#) on page D8-2609.

## D8.8.3 Faults and watchpoints

Table D8-4 lists the faults that might be generated by a write to the Profiling Buffer by the Statistical Profiling Extension.

Writes to the Profiling Buffer never generate watchpoints.

### Table D8-4 Faults

<table>
<thead>
<tr>
<th>Fault</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Translation</td>
<td>The translation of a virtual address to a physical address might generate a Translation fault.</td>
</tr>
<tr>
<td>Address Size</td>
<td>The translation of a virtual address to a physical address might generate an Address Size fault.</td>
</tr>
<tr>
<td>Alignment</td>
<td>If (\text{PMBPTR_EL1}) is not aligned to an [IMPLEMENTATION DEFINED] minimum alignment, the behavior is UNPREDICTABLE and a write to the Profiling Buffer by the Statistical Profiling Extension might generate an Alignment fault. For more information see <a href="#">Restrictions on the current write pointer</a> on page D8-2609.</td>
</tr>
<tr>
<td>Permission</td>
<td>Writes to the Profiling Buffer are made as privileged writes. If the write does not have write permission, a Permission fault is generated. The value of (\text{PSTATE.PAN}) is ignored and treated as zero.</td>
</tr>
</tbody>
</table>
If a write to the Profiling Buffer generates a fault and PMBSR_EL1.S is 0, then a Profiling Buffer management event is generated:

- PMBSR_EL1.S is set to 1.
- PMBSR_EL1.EC is set to one of:
  - 0b100100, stage 1 Data Abort on write to the Profiling Buffer.
  - 0b100101, stage 2 Data Abort on write to the Profiling Buffer.
- The FSC field of PMBSR_EL1.MSS is set as follows:
  - PMBSR_EL1.FSC is set to indicate the type of the fault.
- PMBPTR_EL1 is set to the address that generated the fault.
- If PMBPTR_EL1 is not the address of the first byte after the last complete sample record written by the Statistical Profiling Extension, then PMBSR_EL1.DL is set to 1. Otherwise, PMBSR_EL1.DL is unchanged.
- The other PMBSR_EL1 fields are unchanged.

**Note**

Each of these faults gives rise to a Profiling Buffer management interrupt, not an actual MMU fault exception. The ESR and FAR registers are unchanged.

For more information see *The MMU fault-checking sequence* on page D5-2502.

**Hardware management of dirty state and the Access flag by the Statistical Profiling Extension**

It is IMPLEMENTATION DEFINED whether address translations performed by the Statistical Profiling Extension manage dirty state and the Access flag. This is discoverable by software using PMBIDR_EL1.F. See *Hardware management of dirty state* on page D5-2469 and *Hardware management of the Access flag* on page D5-2468.

If hardware management of dirty state by the Statistical Profiling Extension is implemented, and hardware management of dirty state is enabled for the owning translation regime, then the Statistical Profiling Extension can speculatively update the translation table descriptor for any Page or Block in the Statistical Profiling buffer before writing data to it, if the write is otherwise permitted. This includes the case where a buffer management event means the Statistical Profiling Extension stops writing data before the page or block is written to.

**D8.8.4 External aborts**

A write to the Profiling Buffer might generate an external abort, including an external abort on a translation table walk or translation table update. It is an IMPLEMENTATION DEFINED choice whether such an external abort:

- Is reported to the Statistical Profiling Extension and treated as a Profiling Buffer management event.
- Generates an SError interrupt exception.

If a write to the Profiling Buffer generates an external abort that is reported to the Statistical Profiling Extension:

- The external abort bit, PMBSR_EL1.EA, is set to 1.
The Statistical Profiling Extension stops writing sample records to the Profiling Buffer. It is implementation defined whether an external abort on a write to the Profiling Buffer is reported as synchronous or asynchronous:

- The external abort is reported as **synchronous** if PMBPTR_EL1 is set to the address that was externally aborted.
- The external abort is reported as **asynchronous** if PMBPTR_EL1 is not guaranteed to be set to the address that was externally aborted.

• If the external abort is reported as asynchronous or PMBPTR_EL1 is not the address of the first byte of the sample record being written by the Statistical Profiling Extension, then PMBSR_EL1.DL is set to 1. Otherwise PMBSR_EL1.DL is unchanged.

**Note**

Following an external abort reported asynchronously to the Statistical Profiling Extension, software must not assume that any valid data has been written to the Profiling Buffer.

**Note**

Treating the external abort as a Profiling Buffer management event:

- Sets PMBSR_EL1.S to 1 and so disabling the Statistical Profiling Extension.
- Allows error recovery software to isolate the event to the actions of the Statistical Profiling Extension.

Taking an SError interrupt:

- Means that the Statistical Profiling Extension will only be disabled if the SError interrupt is taken to an Exception level where the Statistical Profiling Extension is disabled.
- Might not allow error recovery software to isolate the event and error containment.
D8.9 Synchronization and Statistical Profiling

The profiling operation of the Statistical Profiling Extension:

- Makes indirect reads and indirect writes of System registers.
- Writes to memory.
- Makes further indirect writes to PMBPTR_EL1 as a result of an external abort on a write to memory.

The indirect reads of the PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} controls when determining whether to select an operation for profiling are treated as indirect reads made by the instruction being executed, and subject to the standard requirements for synchronization.

Otherwise, although the profiling operation is generated by a sampled operation, the profiling operation executes independently of the instructions that are executed on the PE, and acts as a separate memory observer from the PE in the system.

A DSB instruction guarantees that all memory transactions that are made by the PE are observable by writes made by a profiling operation relating to a sampled operation in program order after the DSB instruction.

A Context synchronization event guarantees that a direct write to a System register made by the PE in program order before the context synchronization event are observable by indirect reads and indirect writes of the same System register made by a profiling operation relating to a sampled operation in program order after the context synchronization event.

To synchronize previous profiling operations, software must execute a PSB CSYNC Buffer Synchronization instruction.

--- Note ---

The PSB CSYNC instruction is not defined in the AArch32 instruction set architecture.

---

Following a context synchronization event, a PSB CSYNC instruction is guaranteed to synchronize the profiling operations for all instructions that are executed in program order before the context synchronization event.

Synchronized by the PSB CSYNC instruction means:

- A direct read of a System register in program order following a PSB CSYNC instruction requires explicit synchronization to observe an indirect write to the same System register made by a profiling operation synchronized by the PSB CSYNC instruction.
- An indirect write to a System register made by a profiling operation synchronized by a PSB CSYNC instruction does not affect a direct write to the same System register made in program order following the PSB CSYNC instruction.
- A direct write to a System register in program order following a PSB CSYNC instruction is not allowed to affect an indirect read of the same System register made by a profiling operation synchronized by the PSB CSYNC instruction.
- A DSB instruction in program order following a PSB CSYNC instruction does not complete before the writes to the Profiling Buffer of sample records for profiling operations synchronized by the PSB CSYNC instruction have completed. The DSB instruction must apply to both loads and stores.

For the indirect write to PMBSR_EL1 that is made as a result of an external abort on a write of a sample record to memory, the synchronization rules apply only after the write has completed.

Although the Statistical Profiling Extension acts as another observer in the system, for determining the Shareability domain of the DSB instructions, the writes of sample records are treated as coming from the PE that is being profiled.

--- Note ---

If the Statistical Profiling Extension is not disabled when the context synchronization event occurs, further profiling operations might be generated that are not guaranteed to be synchronized by the PSB CSYNC instruction.

If the PE takes an exception to an Exception level where the Statistical Profiling Extension is disabled, no new operations are selected for sampling. The Statistical Profiling Extension is always disabled if the owning Exception level is a lower Exception level than the current Exception level.
In the absence of a context synchronization event, a **PSB CSYNC** instruction is not required to execute in program order with respect to sampled operations.

**D8.9.1 UNPREDICTABLE behavior**

In the absence of correct context synchronization events, it is UNPREDICTABLE whether an indirect read of a System register made by a profiling operation will return the old or the new values.

If the indirect reads mean that **ProfilingBufferEnabled()** returns FALSE when a sample record or records are about to be written to the physical address, then it is further unpredictable whether the sample record or records:

- Are written to memory.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and a Profiling Buffer management event is generated:
  - **PMBSR_EL1.DL** is set to 1.
  - **PMBSR_EL1.EC** is set to 0x00.
  - **PMBSR_EL1.BSC** is set to 0x00 to indicate that the buffer is not full.

This means that software must execute a **PSB CSYNC** instruction to force any sample records to be written to the Profiling Buffer before changing context.
Chapter D9
Statistical Profiling Extension Sample Record Specification

This chapter describes the sample records generated by the Statistical Profiling Extension. It contains the following sections:

• About the Statistical Profiling Extension Sample Records on page D9-2620.
• Alphabetical list of Statistical Profiling Extension packets on page D9-2623.
D9.1 About the Statistical Profiling Extension Sample Records

The sample record format is self-describing and extensible. This format allows software to parse profile data even when that profile data contains extended information.

The Statistical Profiling Extension writes a series of sample records to memory, each record consisting of a sequence of packets, and each packet consisting of:

- One or two header bytes.
- Zero, 1, 2, 4 or 8 payload bytes.

D9.1.1 Headers

The first header byte encodes the number of payload bytes:

- 0x00–0x1F Single byte header, no payload.
- 0x20–0x3F First byte of extended header. Second byte encodes the payload length.
- 0x40–0x4F, 0x80–0x8F, 0xC0–0xCF 8-bit payload.
- 0x50–0x5F, 0x90–0x9F, 0xD0–0xDF 16-bit payload.
- 0x60–0x6F, 0xA0–0xAF, 0xE0–0xEF 32-bit payload.
- 0x70–0x7F, 0xB0–0xBF, 0xF0–0xFF 64-bit payload.

D9.1.2 Records

A record consists of multiple packets. A record comprises, in ascending address order:

- A sequence of headers, each followed by their payload byte or bytes.
- Either:
  - An end packet header.
  - A timestamp packet.

Figures in this chapter show each packet as a sequence of bytes, with the LSB of each byte to the right and the most significant bit (MSB) to the left. Figure D9-1 shows this convention, and how it relates to data transmission for a packet with a header byte and two payload bytes.

---

Figure D9-1 Convention for packet descriptions

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.
D9.1.3 Byte order

Header bytes and payload bytes are written in ascending address order. Within a payload value, values are written in little-endian byte order.

D9.1.4 Protocol framing packets and forwards compatibility

The padding header, alignment command, timestamp packet, and end packet are protocol framing packets that frame the records created by the Statistical Profiling Extension. Only padding headers and alignment commands are permitted between records.

Note

PMBIDR_EL1.Align defines a minimum alignment for records. However, implementations must nevertheless create a valid protocol stream that can be parsed without knowledge of the minimum alignment.

The packet types are described in the following sections. Software must ignore unknown packets, using the size field encoded in the header. This includes packets containing reserved values in fields.

The following sections give an overview of the Statistical Profiling Extension packets and how the TPIU transmits them:

- Statistical Profiling Extension protocol packet headers

Note

This chapter describes packet transmission by a trace sink such as a TPIU. The Statistical Profiling Extension can send packets to any suitable trace sink. Regardless of the actual trace sink used, the Statistical Profiling Extension formats the packets as described in this chapter.

D9.1.5 Statistical Profiling Extension protocol packet headers

8-bit headers

For Address packets and Counter packets, the 8-bit header format is described as the short format.

D9.2 Alphabetical list of Statistical Profiling Extension packets

D9.2.1 Address packet

The Address packet characteristics are:

**Purpose**
Provides an address value for the record. Addresses are always 64 bits.

**Attributes**
Multi-part packet comprising:
- 8 or 16-bit header.
- 64-bit payload.

**Address packet header**

When Extended format is used, the Address packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>INDEX[2:0]</td>
<td></td>
</tr>
</tbody>
</table>

When Short format is used, the Address packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>

**Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format**

This field reads as 0b10.

**SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format**

Payload size. The defined values of this field are:
- 0b11 Doubleword.
  - This field reads as 0b11.

**Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format**

This bit reads as 0b0.

**Byte 0 bits [7:5], when Extended format**

This field reads as 0b001.

**Byte 0 bits [4:2], when Extended format**

This field reads-as-zero.

**INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format**

The defined values of this field are:
- 0b00000 Issued instruction virtual address (PC). Included for all operations.
- 0b00001 Branch target address:
  - It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this address is included for an Exception Return to an Exception level where profiling is disabled.
  - Included for all other branch and exception return instructions.
0b00010 Data access virtual address. Included for all load, store and atomic operations.

0b00011 Data access physical address:

- It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this address included for accesses that generate Permission or Access Flag faults.
- Not included for all other accesses that generate an abort, or if disabled by CollectPhysicalAddress.
- Included for all other load, store and atomic operations.

0b0011x IMPLEMENTATION DEFINED address.

0b1xxxx IMPLEMENTATION DEFINED address.

All other values are reserved.

In the Short format header, bits [4:3] are zero.

**Address packet payload**

When Data access physical address, the Address packet payload bit assignments are:

```

<table>

**TAG byte<7>, when Data access virtual address**

Top-byte tag.

If the value of the applicable TBI bit is one, a data access virtual address includes the top-byte tag. If the applicable TBI bit is zero, it is IMPLEMENTATION DEFINED whether this field reads as zero or holds the address tag of the applicable address.
NS, byte 7 bit [7], when Instruction virtual address

Non-secure state. The Security state associated with the address. For an issued instruction virtual address (PC) this is the Security state the instruction was executed in. For a branch target address, this is the Security state at the target of the branch. The defined values of this bit are:

0  Secure state.
1  Non-secure state.

Note
For an Exception Return, the Security state at the target of the branch might be different to the Security state the instruction was executed in.

NS, byte 7 bit [7], when Data access physical address

Physical address space identifier. The Security attribute for the physical address. The defined values of this bit are:

0  Secure physical address space.
1  Non-secure physical address space.

EL, byte 7 bits [6:5], when Instruction virtual address

Exception level. The Exception level associated with the address. For an issued instruction virtual address (PC) this is the Exception level the instruction was executed in. For a branch target address, this is the Exception level at the target of the branch. The defined values of this field are:

0b00  EL0.
0b01  EL1.
0b10  EL2.
0b11  EL3.

Note
For an Exception Return, the Exception level at the target of the branch might be different to the Exception level the instruction was executed in.

Byte 7 bits [6:0], when Data access physical address

This field reads as 0b000000.

Byte 7 bits [4:0], when Instruction virtual address

This field reads as 0b00000.

ADDR, bytes <6:0>

D9.2.2  **Alignment command**

The Alignment command characteristics are:

**Purpose**  Allows the PE to create alignment to a naturally aligned address boundary in the buffer for the next protocol byte. Alignment bytes must be ignored.

**Attributes**  16-bit packet.

**Field descriptions**

The Alignment command bit assignments are:

```
+-------------------+-------------------+-----------------+
<p>|    7   6   5   4   3   2   1   0    |
|-------------------|-------------------|-----------------|</p>
<table>
<thead>
<tr>
<th>0   0   1   0</th>
<th>SIZE</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0   0   0   0   0</td>
<td>0   0</td>
<td>Byte 1</td>
</tr>
</tbody>
</table>
```

**Byte <1>**

This field reads as \(0b00000000\).

**Byte 0 bits [7:5]**

This field reads as \(0b001\).

**Byte 0 bit [4]**

This bit reads-as-zero.

**SIZE, byte 0 bits [3:0]**

Defines the alignment of the next protocol byte. The data between the Alignment command and the next header byte is UNKNOWN. The defined values of this field are:

- \(0b0001\) 4 byte alignment.
- \(0b0010\) 8 byte alignment.
- \(0b0011\) 16 byte alignment.
- ...  ...
- \(0b1111\) 64 Kbyte alignment.

All other values are reserved.

**Note**

The address of the next protocol byte is aligned to a multiple of the specified size. There will always be fewer than this number of bytes between the Alignment command and the next protocol byte.
D9.2.3 Context packet

The Context packet characteristics are:

**Purpose**
Provides context information for the record.

**Attributes**
Multi-part packet comprising:
- 8-bit header.
- 32-bit payload.

**Context packet header**

The Context packet header bit assignments are:

<table>
<thead>
<tr>
<th>Byte 0 bits [7:6]</th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field reads as 0b01.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SZ, byte 0 bits [5:4]</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field reads as 0b10.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Byte 0 bits [3:2]</th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field reads as 0b01.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>INDEX, byte 0 bits [1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
</tr>
<tr>
<td>0b01</td>
</tr>
<tr>
<td>All other values are reserved.</td>
</tr>
</tbody>
</table>

**Context packet payload**

The Context packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXT[7:0]</td>
</tr>
<tr>
<td>Byte 1</td>
</tr>
<tr>
<td>CONTEXT[15:8]</td>
</tr>
<tr>
<td>Byte 2</td>
</tr>
<tr>
<td>CONTEXT[23:16]</td>
</tr>
<tr>
<td>Byte 3</td>
</tr>
<tr>
<td>CONTEXT[31:24]</td>
</tr>
</tbody>
</table>

**CONTEXT, bytes <3:0>**
The context value.
D9.2.4 Counter packet

The Counter packet characteristics are:

**Purpose**
Count of cycles the operation spent performing all or part of its behavior. The counter value occupies the least significant bits of the payload. The remaining bits are set to zero.

**Attributes**
Multi-part packet comprising:
- 8 or 16-bit header.
- 16-bit payload.

**Counter packet header**

When Extended format, the Counter packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>INDEX[4:3]</td>
</tr>
</tbody>
</table>

When Short format, the Counter packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>INDEX[2:0]</td>
</tr>
</tbody>
</table>

**Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format**

This field reads as 0b10.

**SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format**

Payload size. The defined values of this field are:

- 0b01 Halfword.
  This field reads as 0b01.

**Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format**

This bit reads as 0b1.

**Byte 0 bits [7:5], when Extended format**

This field reads as 0b01.

**Byte 0 bits [4:2], when Extended format**

This field reads-as-zero.

**INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format**

The defined values of this field are:

- 0b00000 Total latency. Cycle count from the operation being dispatched for issue to the operation being complete. Included for all operations.
- 0b00001 Issue latency. Cycle count from the operation being dispatched for issue to the operation being issued for execution. This counts any delay in waiting the operation being ready to issue. Included for all operations.
- 0b00010 Translation latency. Cycle count from a virtual address being passed to the MMU for translation to the result of the translation being available. Included for all load, store and atomic operations.
- 0b0011x IMPLEMENTATION DEFINED counter value.
0b1xxxx IMPLEMENTATION DEFINED counter value.
All other values are reserved.

In the Short format header, bits [4:3] are zero.

Dispatched for issue means:
• The operation has been decoded.
• The operation might not be ready to start execution because it is waiting for input values. The operation might be put into a queue.

Issued for execution means the operation is ready to start executing:
• For example, for a memory operation, this should be indicative of the cycle count from memory operation being dispatched for issue to access being initiated (virtual address).

Complete means:
• The operation has completed execution and is no longer capable of stalling any instruction that consumes its output.
• It is IMPLEMENTATION DEFINED whether the operation has committed its results to the architectural state of the PE.
• For example:
  — For an arithmetic, floating-point, or SIMD operation with variable timing, such as divide, the results of the operation are available.
  — For load and atomic operations that return data, all data have been returned from memory.
  — For store and atomic operations that do not return data, it is not required that the store has reached its end point for it to be complete.
  — For branch operations, the branch has been resolved as taken or not taken.
  — For barrier operations, the barrier has completed.

For WFE and WFI operations, it is IMPLEMENTATION DEFINED whether:
• The instruction is complete before the PE enters a low-power state or when the PE wakes from the low-power state.
• Counters count in the low power state.
• Sampling an operation is itself a wake-up event.

Counter packet payload

The Counter packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COUNT[7:0]</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>COUNT[11:8]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Byte 1 bits [7:4]

This field reads-as-zero.

COUNT, byte 1 bits [3:0], byte <0>, when a 12-bit counter is implemented

The counter value occupies the least significant bits of the payload. The remaining bits are set to zero. The counters are:
• Unsigned numbers.
• 12 bits.
• Saturating.

The value 0xFFF indicates the count has saturated.
D9.2.5 Data Source packet

The Data Source packet characteristics are:

**Purpose**
If the implementation includes support for indicating the loaded data source, the Data Source packet indicates where the data returned for a load operation was sourced. It might also include other information, such as the state of the data at the source. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this is included for load and atomic operations that generate an external abort. It is IMPLEMENTATION DEFINED whether this is included for atomic operations that do not return data to a PE register. Included for all other load and atomic operations.

**Attributes**
Multi-part packet comprising:
- 8-bit header.
- 8 or 16-bit payload.

Data Source packet header

The Data Source packet header bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>0</td>
<td>1</td>
<td>SZ</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

**Byte 0 bits [7:6]**
This field reads as 0b01.

**SZ, byte 0 bits [5:4]**
Payload size. The defined values of this field are:
- 0b00 Byte.
- 0b01 Halfword.

**Byte 0 bits [3:0]**
This field reads as 0b0011.

Data Source packet payload

When SZ == 0b00, the Data Source packet payload bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>SOURCE</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When SZ == 0b01, the Data Source packet payload bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>SOURCE[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Byte 1</td>
<td>SOURCE[15:8]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SOURCE, byte <0>, when SZ == 0b00, SOURCE, bytes <1:0>, when SZ == 0b01**

Because the list of data sources varies from system to system, the definition of this field is IMPLEMENTATION DEFINED. If a sampled operation generated multiple data accesses, it is IMPLEMENTATION DEFINED how the data source information is combined.
### D9.2.6 End packet

The End packet characteristics are:

- **Purpose**: Defines the end of a record if a Timestamp packet is not present.
- **Attributes**: 8-bit packet.

#### Field descriptions

The End packet bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

**Byte <0>**

This field reads as `0b0000001`. 

---

**Data Sheet**: D9-2632  
**Copyright © 2013-2018 ARM Limited or its affiliates. All rights reserved.**  
**Non-Confidential**
D9.2.7   Events packet

The Events packet characteristics are:

**Purpose**
Indicates up to 64 events generated by the sampled operation.

**Attributes**
Multi-part packet comprising:
- 8-bit header.
- 8, 16, 32, or 64-bit payload.

**Events packet header**

The Events packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>SZ</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Byte 0 bits [7:6]**
This field reads as \(0b01\).

**SZ, byte 0 bits [5:4]**
Payload size. The defined values of this field are:
- \(0b00\)  Byte.
- \(0b01\)  Halfword.
- \(0b10\)  Word.
- \(0b11\)  Doubleword.

Software must treat bits that are not output as zero.

**Byte 0 bits [3:0]**
This field reads as \(0b0010\).

**Events packet payload**

When \(SZ = 0b00\), the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

When \(SZ = 0b01\), the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>
When \( \text{SZ} = 0b10 \), the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
</tr>
<tr>
<td>9</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>12</td>
<td>0</td>
</tr>
</tbody>
</table>

When \( \text{SZ} = 0b11 \), the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
</tr>
<tr>
<td>9</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>12</td>
<td>0</td>
</tr>
</tbody>
</table>

\( E[63:48] \), bytes <7:6>, when \( \text{SZ} = 0b11 \)

Events 63 to 48. IMPLEMENTATION DEFINED.

\( E[55:48] \), byte <3>, when \( \text{SZ} = 0b10 \), or when \( \text{SZ} = 0b11 \)

Events 31 to 24. IMPLEMENTATION DEFINED.

\( E[31:24] \), byte <2>, byte 1 bit [3], when \( \text{SZ} = 0b11 \)

This field reads-as-zero.

\( E[15:12] \), byte 1 bits [7:4], when \( \text{SZ} = 0b01 \), when \( \text{SZ} = 0b10 \), or when \( \text{SZ} = 0b11 \)

Events 15 to 12. IMPLEMENTATION DEFINED.

\( E[63:56] \), byte 1 bit [3], when \( \text{SZ} = 0b01 \)

This bit reads-as-zero.
E[10], byte 1 bit [2], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11
Remote access. The defined values of this bit are:
0  Did not cause access to another socket.
1  Load/store operation caused an access to another socket in a multi-socket system. This includes each data memory access that accesses another socket in a multi-socket system, including those that do not return data.

— Note ——
See also REMOTE_ACCESS.

E[9], byte 1 bit [1], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11
Last Level cache miss. The defined values of this bit are:
0  Did not miss Last Level cache.
1  Load/store operation caused an access to at least the Last Level cache but is not completed by the Last Level cache. That is, each:
   • Load operation that does not return data from the Last Level cache.
   • Store operation that does not update the Last Level cache.
   The event is not set for operations that are completed by a cache above the Last Level cache.

— Note ——
See also LL_CACHE_MISS.

E[8], byte 1 bit [0], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11
Last Level cache access. The defined values of this bit are:
0  Did not access Last Level data or unified cache.
1  Load/store operation caused a cache access to at least the Last Level data or unified cache.

— Note ——
The architecture does not define the Last Level cache. The Last Level cache is typically the largest cache on this device shared by all PEs in the inner or outer Shareable domain of this PE. In a multi-socket system, it is IMPLEMENTATION DEFINED whether this includes caches on other sockets.

— Note ——
See also LL_CACHE.

E[7], byte 0 bit [7]
Mispredicted. The defined values of this bit are:
0  Did not cause correction to the predicted program flow.
1  A branch that caused a correction to the predicted program flow.

E[6], byte 0 bit [6]
Not taken. The defined values of this bit are:
0  Did not fail condition code check.
1  A conditional instruction that failed its condition code check. This includes conditional branches, compare-and-branch, conditional select, and conditional compares:
   • For a conditional branch or compare-and-branch instruction, this means the branch was not taken.
   • For a conditional select, this means the second operand was written to the result.
• For a condition compare, this means the condition flags were set to the immediate value and not the result of the compare.

E[5], byte 0 bit [5]

TLB walk. The defined values of this bit are:

0   Did not generate TLB walk.
1   Load/store operation that causes a refill of a data or unified TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

—— Note ———
See also DTLB_WALK.

E[4], byte 0 bit [4]

TLB access. The defined values of this bit are:

0   Did not access TLB.
1   Load/store operation caused an access to at least the first level of data or unified TLB.

—— Note ———
See also L1D_TLB.

E[3], byte 0 bit [3]

Level 1 Data cache refill. The defined values of this bit are:

0   Did not cause level 1 data cache refill.
1   Load/store operation caused a refill of at least the first level of data or unified cache. This includes each data memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

—— Note ———
See also L1D_CACHE_REFILL.

E[2], byte 0 bit [2]

Level 1 Data cache access. The defined values of this bit are:

0   Did not access level 1 data cache.
1   Load/store operation caused a cache access to at least the first level of data or unified cache.

—— Note ———
See also L1D_CACHE.

E[1], byte 0 bit [1]

Architecturally retired. The defined values of this bit are:

0   Did not retire.
1   Committed its results to the architectural state of the PE, or completed with a synchronous architectural exception.

—— Note ———
A conditional instruction can retire even if it fails its condition code check.
E[0], byte 0 bit [0]

Generated exception. The defined values of this bit are:

0  Did not generate an exception.
1  Completed with a synchronous exception.

If E[1] in the same Events packet is set to 0, then the meaning of this bit is IMPLEMENTATION DEFINED.
D9.2.8 Operation Type packet

The Operation Type packet characteristics are:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Defines the type of operation sampled. Included for all operations.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes</td>
<td>Multi-part packet comprising:</td>
</tr>
<tr>
<td></td>
<td>• 8-bit header.</td>
</tr>
<tr>
<td></td>
<td>• 8-bit payload.</td>
</tr>
</tbody>
</table>

Operation Type packet header

The Operation Type packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8-bit header.</td>
<td>0b01</td>
</tr>
<tr>
<td>1</td>
<td>Payload size.</td>
<td>0b00 (Byte)</td>
</tr>
<tr>
<td>2</td>
<td>Top-level instruction class.</td>
<td>0b10</td>
</tr>
<tr>
<td>3</td>
<td>Other.</td>
<td>0b00</td>
</tr>
<tr>
<td>4</td>
<td>Load, store, or atomic.</td>
<td>0b01</td>
</tr>
<tr>
<td>5</td>
<td>Branch or exception return.</td>
<td>0b10</td>
</tr>
<tr>
<td>6</td>
<td>All other values are reserved.</td>
<td></td>
</tr>
</tbody>
</table>

Operation Type packet payload (Other)

The Operation Type packet payload (Other) bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Second-level instruction class. Defines the type of instruction.</td>
<td>0x00 (Other)</td>
</tr>
<tr>
<td>1</td>
<td>Other (unconditional) instruction.</td>
<td>0x00</td>
</tr>
<tr>
<td>2</td>
<td>Conditional instruction or select.</td>
<td>0x01</td>
</tr>
<tr>
<td>3</td>
<td>All other values are reserved.</td>
<td></td>
</tr>
</tbody>
</table>
**Operation Type packet payload (Branch)**

The Operation Type packet payload (Branch) bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBCLASS, byte &lt;0&gt;</td>
<td>COND</td>
<td>Byte 0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**COND, byte 0 bit [0]**

Conditional. The defined values of this bit are:

- **0** Unconditional branch.
- **1** Conditional branch.

**SUBCLASS, byte <0>**

Second-level instruction class. Describes the branch type. The defined values of this field are:

- **0b0000000x** Direct branch.
- **0b0000001x** Indirect branch.
- All other values are reserved.

**Operation Type packet payload (Load/store)**

When Extended load/store, the Operation Type packet payload (Load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBCLASS, byte &lt;0&gt;</td>
<td>AR</td>
<td>EXCL</td>
<td>AT</td>
<td>1</td>
<td>LDST</td>
<td>Byte 0</td>
<td></td>
</tr>
</tbody>
</table>
```

When General-purpose load/store, the Operation Type packet payload (Load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBCLASS, byte &lt;0&gt;</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>LDST</td>
</tr>
</tbody>
</table>
```

When SIMD&FP load/store, the Operation Type packet payload (Load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBCLASS, byte &lt;0&gt;</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>LDST</td>
</tr>
</tbody>
</table>
```

**SUBCLASS, byte <0>**

Second-level instruction class. Indicates the load/store type. The defined values of this field are:

- **0b0000000x** A load/store targeting the general-purpose registers, other than an atomic operation, load-acquire, store-release or exclusive.
- **0b000xxx1x** An atomic operation, load-acquire, store-release or exclusive. Bits [4:2] are further subdivided as described by the AR, EXCL and AT fields.
- **0b0000010x** A load/store targeting the SIMD&FP registers.
- All other values are reserved.
AR, byte 0 bit [4], when Extended load/store

Acquire/Release. The defined values of this bit are:
0    Load/store/atomic without Acquire or Release semantics.
1    Load/store/atomic with Acquire or Release semantics.

EXCL, byte 0 bit [3], when Extended load/store

Exclusive. The defined values of this bit are:
0    Load/store/atomic without Exclusive.
1    Load/store with Exclusive.

This bit is res0 if AT == 1.

AT, byte 0 bit [2], when Extended load/store

Atomic load/store. The defined values of this bit are:
0    Not atomic.
1    Atomic.

LDST, byte 0 bit [0]

Store not load. The defined values of this bit are:
0    Load or swap.
1    Store.
D9.2.9 Padding

The Padding characteristics are:

**Purpose**
Allows the PE to create alignment in the protocol buffer.

**Attributes**
8-bit packet.

**Field descriptions**

The Padding bit assignments are:

```
     7 6 5 4 3 2 1 0
  0 0 0 0 0 0 0 0  Byte 0
```

Byte <0>

This field reads as `0b00000000`. 
D9.2.10  Timestamp packet

The Timestamp packet characteristics are:

**Purpose**

The 64-bit timestamp value when the operation was sampled. The Timestamp packet must come at the end of the record. If the Timestamp packet is not present, an End packet must come at the end of the record.

**Attributes**

Multi-part packet comprising:
- 8-bit header.
- 64-bit payload.

**Timestamp packet header**

The Timestamp packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

**Byte 0 bits [7:6]**

This field reads as `0b01`.

**SZ, byte 0 bits [5:4]**

Payload size. The defined values of this field are:
- `0b11` Doubleword.
  This field reads as `0b11`.

**Byte 0 bits [3:0]**

This field reads as `0b0001`. 
**Timestamp packet payload**

The Timestamp packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Offset</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TS[7:0]</td>
<td>Byte 0</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[15:8]</td>
<td>Byte 1</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[23:16]</td>
<td>Byte 2</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[31:24]</td>
<td>Byte 3</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[39:32]</td>
<td>Byte 4</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[47:40]</td>
<td>Byte 5</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[55:48]</td>
<td>Byte 6</td>
<td>0x0</td>
</tr>
<tr>
<td>TS[63:56]</td>
<td>Byte 7</td>
<td>0x0</td>
</tr>
</tbody>
</table>

**TS, bytes <7:0>**

Timestamp value when the operation was sampled. The value depends on the result of `aarch64/debug/statisticalprofiling/CollectRecord()`:

- If TimeStamp_Virtual, this is the virtual timestamp, CNTVCT_EL0.
- If TimeStamp_Physical, this is the physical timestamp, CNTPCT_EL0.
- If TimeStamp_None, the timestamp packet is not included and an End packet must come at the end of the record.

However, if the Generic Timer System counter is disabled and `aarch64/debug/statisticalprofiling/CollectTimeStamp()` returns a value other than TimeStamp_None, then it is IMPLEMENTATION DEFINED whether:

- The Statistical Profiling Extension behaves as if `aarch64/debug/statisticalprofiling/CollectTimeStamp()` returns the value TimeStamp_None.
- The value of this field in the record is UNKNOWN.

--- **Note** ---

This relaxation refers to when the actual System counter is disabled, that is, CNTEN.EN == 0. It does not apply when the System counter is enabled but not accessible at the current Exception level.
D9 Statistical Profiling Extension Sample Record Specification
D9.2 Alphabetical list of Statistical Profiling Extension packets
Chapter D10
The Generic Timer in AArch64 state

This chapter describes the implementation of the ARM Generic Timer. It includes an overview of the AArch64 System register interface to an ARM Generic Timer.

It contains the following sections:

• About the Generic Timer on page D10-2646.
• The AArch64 view of the Generic Timer on page D10-2650.

Chapter G6 The Generic Timer in AArch32 state describes the AArch32 view of the Generic Timer, and Chapter I2 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
D10.1 About the Generic Timer

Figure D10-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The ARM Generic Interrupt Controller Architecture Specification defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

  **Note**

  The Generic Timer can also provide other components at a system level, but Figure D10-1 does not show any such components.

- Supports virtual counters that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.

- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D10-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G6 The Generic Timer in AArch32 state describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D10-1

  Optionally, can provide timer components for use at a system level.

Chapter I2 System Level Implementation of the Generic Timer describes this memory-mapped component.
D10.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see The system counter on page D10-2648. Because this must be implemented at the system level, it is accessed through The system level memory-mapped implementation of the Generic Timer. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

• A physical counter, that gives access to the count value of the system counter.
• A virtual counter, that gives access to virtual time. In AArch64 state, the CNTVOFF_EL2 register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
• A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
  — An EL1 physical timer.
  — A Non-secure EL2 physical timer.
  — An EL3 physical timer.
  — An EL1 virtual timer.
  — A Non-secure EL2 virtual timer.
  — A Secure EL2 virtual timer.
  — A Secure EL2 physical timer.

The Non-secure EL2 virtual timer is available only when ARMv8.1-VHE is implemented. The Secure EL2 timers are available only when ARMv8.4-SecEL2 is implemented.

The AArch64 view of the Generic Timer on page D10-2650 describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into frames. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

  • A control frame, CNTControlBase.
  • A status frame, CNTReadBase.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

  • Which timers are implemented.
  • The features of each implemented timer.

This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional

An implemented memory-mapped timer:

  • Must provide a privileged view of the timer, in the CNTBaseN frame.
  • Optionally, provides an unprivileged view of the timer in the CNTEL0BaseN frame.

N is the timer number, and the corresponding frame number, in the range 0-7.
The Generic Timer provides a system counter with the following specification:

- **Width**: At least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.
- **Frequency**: Increments at a fixed frequency, typically in the range 1-50MHz. Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.
- **Roll-over**: Roll-over time of not less than 40 years.
- **Accuracy**: ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy.
- **Start-up**: Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The CNTFRQ_EL0 register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information, see Initializing and reading the system counter frequency.

The mechanism by which the count from the system counter is distributed to system components is implementation defined, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

---

**Note**

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray-count scheme for timer distribution scheme on page K5-7274 gives more information about this possibility.

---

### Initializing and reading the system counter frequency

The CNTFRQ_EL0 register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the CNTFRQ_EL0 register. Only software executing at the highest implemented Exception level can write to CNTFRQ_EL0.

---

**Note**

The CNTFRQ_EL0 register is **UNKNOWN** at reset, and therefore the counter frequency must be set as part of the system boot process.
Software can read the CNTFRQ_EL0 register, to determine the current system counter frequency, in the following states:

- Secure and Non-secure EL2.
- Secure and Non-secure EL1.
- When CNTKCTL_EL1.EL0PCTEN is set to 1, Secure and Non-secure EL0.

**Memory-mapped controls of the system counter**

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter 12 *System Level Implementation of the Generic Timer*. 
D10.2  The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- **The physical counter.**
- **The virtual counter.**
- **Event streams** on page D10-2651.
- **Timers** on page D10-2652.

D10.2.1  The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT_EL0 register holds the current physical counter value.

Reads of CNTPCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTPCT_EL0 must be read, an ISB is used to ensure that the read of CNTPCT_EL0 occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]          
    CMP R1, #1   
    BNE loop      
    ISB             ; without this, the CNTPCT could be read before the memory location in [R2]
               ; has had the value 1 written to it
    MRS R1, CNTPCT
```

D10.2.2  The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at EL1 or EL0, the virtual offset value relates to the current virtual machine.

The CNTVOFF_EL2 register contains the virtual offset. CNTVOFF_EL2 is only accessible from EL2 and EL3.

For more information, see **Status of the CNTVOFF register**.

The CNTVCT_EL0 register holds the current virtual counter value.

Reads of CNTVCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTVCT_EL0 must be read, an ISB is used to ensure that the read of CNTVCT_EL0 occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]          
    CMP R1, #1   
    BNE loop      
    ISB             ; without this, the CNTVCT could be read before the memory location in [R2]
               ; has had the value 1 written to it
    MRS R1, CNTVCT
```

**Status of the CNTVOFF register**

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF_EL2 register that defines the virtual offset between the physical count and the virtual count. CNTVOFF_EL2 is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.
D10.2.3 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in Wait for Event mechanism and Send event on page D1-2255.

Note

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The CNTKCTL_EL1.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations, the CNTHCTL_EL2.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:
  
  // Variables used for generation of the timer event stream.
  // bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
  // bits(64) PreviousCNTPCT = bits(64) UNKNOWN;

- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.

- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

  // TestEventCNTx()  
  // ===============
  // Template for the TestEventCNTV() and TestEventCNTP() functions
  // Describes operation when all Exception Levels are using AArch64:
  // CNTxCT_EL0         is  CNTVCT_EL0          or  CNTPCT_EL0          64-bit count value
  // CNTx_CTL_EL0       is  CNTV_CTL_EL0        or  CNTP_CTL_EL0        Control register
  // PreviousCNTxCT_EL0 is  PreviousCNTVCT_EL0  or  PreviousCNTPCT_EL0

  TestEventCNTx()
  if CNTx_CTL_EL0.EVNTEN == '1' then
      n = UInt(CNTx_CTL_EL0.EVNTI);
      SampleBit = CNTxCT_EL0<n>;
      PreviousBit = PreviousCNTxCT_EL0<n>;

      if CNTx_CTL_EL0.EVNTDIR == '0' then
          if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
          else if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();
      PreviousCNTxCT_EL0 = CNTxCT_EL0;
  return;
D10.2.4 Timers

In an implementation of the Generic Timer that includes EL3, if EL3 can use AArch64, the following timers are implemented:

- An EL1 physical timer, that:
  - In Secure state, can be accessed from EL1.
  - In Non-secure state, can be accessed from EL1 unless those accesses are trapped to EL2.
  
  When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.

- A Non-secure EL2 physical timer.
- A Secure EL3 physical timer. An EL3 control determines whether this register is accessible from Secure EL1.
- An EL1 virtual timer.
- A Non-secure EL2 virtual timer, when ARMv8.1-VHE is implemented.
- A Secure EL2 physical timer, when ARMv8.4-SecEL2 is implemented, that can only be accessed in Secure EL2 and EL3.
- A Secure EL2 Virtual timer, when ARMv8.4-SecEL2 is implemented, that can only be accessed in Secure EL2 and EL3.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a Generic Interrupt Controller (GIC), signals a Private Peripheral Interrupt (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
- Has, in addition, a 32-bit Control register.

<sup>c</sup> Only present when the implementation includes ARMv8.4-SecEL2.
Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, CNTV_CTL_EL0, or CNTHVS_CTL_EL2. For CNTP_CTL_EL0, the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch32 register CNTP_CTL.

The operation of this view of a timer is:

\[
\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)
\]

Where:
- **TimerConditionMet** is TRUE if the timer condition for this counter is met, and FALSE otherwise.
- **Counter** is the physical counter value, that can be read from the CNTPCT_EL0 register.
- **Offset** is zero for a physical timer, this value is held in the CNTVOFF_EL2 register.
- **CompareValue** is the value of the appropriate CompareValue register, CNTP_CV_AL_EL0, CNTHP_CV_AL_EL2, CNTHPS_CV_AL_EL2, CNTPS_CV_AL_EL1, CNTV_CV_AL_EL0, or CNTHV_CV_AL_EL2.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

Note

This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Software can observe the counter value by the offset in some situations by reading CNTVCT_EL0. For more information see CNTVCT_EL0.

Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, or CNTV_CTL_EL0, CNTHVS_CTL_EL2.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

**Reads**

\[
\text{TimerValue} = ((\text{Counter} - \text{Offset})[63:0] + \text{SignExtend}(\text{TimerValue})[63:0])
\]

**Writes**

\[
\text{CompareValue} = ((\text{Counter} - \text{Offset})[31:0] + \text{SignExtend}(\text{TimerValue})[31:0])
\]

Where the arguments other than TimerValue have the definitions used in *Operation of the CompareValue views of the timers*, and in addition:

- **TimerValue** is the value of a TimerValue register, CNTP_TV_AL_EL0, CNTHP_TV_AL_EL2, CNTHPS_TV_AL_EL2, CNTPS_TV_AL_EL1, CNTV_TV_AL_EL0, or CNTHV_TV_AL_EL2.

In this view of a timer, values are signed in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.
Note

- Operation of the CompareValue views of the timers on page D10-2653 gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:
  \[ \text{TimerConditionMet} = (\text{TimerValue} \leq 0) \]

- Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
Chapter D11
AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- *The System register encoding space on page D11-2656.*
- *op0==0b10, Moves to and from debug and trace System registers on page D11-2657.*
- *op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D11-2659.*
The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in Chapter D12 AArch64 System Register Descriptions.

Note

- See Fixed values in AArch64 instruction and System register descriptions on page C2-165 for information about abbreviations used in the System instruction descriptions.

In AArch32 state much of this functionality is provided through the System register interface described in The AArch32 System register interface on page G1-5305. In AArch64 state, the parameters used to characterize the System register encoding space are \{op0, op1, CRn, CRm, op2\}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface on page G1-5306. In ARMv8, there is no particular significance to the naming of these parameters, and no functional distinction between the opn parameters and the CRx parameters.

Principles of the System instruction class encoding on page C5-338 describes some general properties of these encodings. System instruction class encoding overview on page C5-339 then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set \{op0, op1, CRn, CRm, op2\}.
- op0 is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in Chapter C5 The A64 System Instruction Class. This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- op0==0b10, Moves to and from debug and trace System registers on page D11-2657.
- op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D11-2659.
**D11.2 op0==0b10, Moves to and from debug and trace System registers**

The instructions that move data to and from the debug, Execution environment, and trace System registers are encoded with op0==0b10. This means the encoding of these instructions is:

| 31 30 29 28| 27 26 25 24| 23 22 21 20| 19 18 16| 15| 12| 11| 8 7 5 4 | 0 |
|--------------|--------------|--------------|--------|----|----|----|--------|
| 1 1 0 1 0 1 0 0 | L 1 0 | op1 | CRn | CRm | op2 | Rt |

**Note**

- The section describes the use of all of the op0==0b10 region of the System register encoding space.
- These encodings access the registers that are equivalent to the AArch32 System registers in the (coproc==0b1110) encoding space.

The value of op1 provides the next level of decode of these instructions, as follows:

- **op1 == {0, 3, 4}**
  - Debug. See *Instructions for accessing debug System registers*

**Note**

The standard encoding of debug registers is op0==0b10, op1=={0, 3, 4}. The registers in the op0==0b11 encoding space that are classified as debug registers are DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3. See *Instructions for accessing non-debug System registers* on page D11-2659 for the encodings of these registers.

- **op1 == 1**  Trace. See the appropriate trace architecture specification.

**D11.2.1 Instructions for accessing debug System registers**

The instructions for accessing debug System registers are:

- MSR <System register>, Xt ; Write to System register
- MRS Xt, <System register> ; Read from System register

Where <System register> is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:

- op0 is 0b10.
- The value of op1 is one of {0, 3, 4}.

**Note**

These encodings access the registers that are equivalent to the AArch32 System registers in the (coproc==0b1110) encoding space.
Table D11-1 shows the mapping of the System register encodings for debug System register access.

</table>

a. Unimplemented breakpoint and watchpoint register access instructions are unallocated. CRm encodes \(<n>\), the breakpoint or watchpoint number.

For more information see *Mapping of the System registers between the Execution states* on page D1-2266.
D11.3  \( \text{op0} = 0b11 \), Moves to and from non-debug System registers, Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with \( \text{op0} = 0b11 \), except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

\[
\begin{array}{cccccccccccccc}
1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & L & 1 & 1 & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} & \text{Rt} \\
\end{array}
\]

The value of \( \text{CRn} \) provides the next level of decode of these instructions, as follows:

- \( \text{CRn} = \{0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14\} \)
  - See Instructions for accessing non-debug System registers.

- \( \text{CRn} = 4 \)
  - See Instructions for accessing Special-purpose registers on page C5-348.

- \( \text{CRn} = \{11, 15\} \)
  - See Reserved encodings for IMPLEMENTATION DEFINED registers on page D11-2671.

D11.3.1  Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

- \text{MSR } \langle\text{System register}\rangle, \text{Xt} \); Write to System register
- \text{MRS } \text{Xt}, \langle\text{System register}\rangle \); Read from System register

Where \( \langle\text{System_register}\rangle \) is the register name, for example \( \text{MIDR} \_\text{EL1} \).

This section includes only the System register access encodings for which both:

- \( \text{op0} = 0b11 \).
- The value of \( \text{CRn} \) is one of \( \{0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14\} \).

\[\text{Note}\]

These encodings access the registers that are equivalent to the AArch32 System registers in the \( \text{coproc} = 0b1111 \) encoding space.

While this group is described as accessing the non-debug System registers, its correct characterization is by the \( \{\text{op0}, \text{CRn}\} \) values given in this subsection, and the group includes the debug registers \( \text{DLR} \_\text{EL0}, \text{DSPSR} \_\text{EL0}, \text{MDCR} \_\text{EL2}, \text{MDCR} \_\text{EL3}, \) and \( \text{SDER32} \_\text{EL3} \), that are described in Debug registers on page D12-3210. These registers are exceptions to the standard encoding of debug registers, that has \( \text{op0} = 0b10 \), see Instructions for accessing debug System registers on page D11-2657.

The instruction encoding for these accesses is:

\[
\begin{array}{cccccccccccccc}
1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & L & 1 & 1 & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} & \text{Rt} \\
\end{array}
\]

See text for permitted values of \( \text{CRn} \)

Table D11-2 on page D11-2660 shows the encodings of the register access instructions. In the Notes on page D11-2660 column of the table:

- **Config-RO**  Means it is configurable whether read accesses are permitted. Write accesses are UNDEFINED.
- **Config-WO**  Means it is configurable whether write accesses are permitted. Read accesses are UNDEFINED.
- **Config-RW**  Means it is configurable whether accesses are permitted. Either read and write accesses are permitted, or read and write accesses are UNDEFINED.

See the register descriptions for information about the control that determines whether these accesses are permitted.

* a. Scalable Vector Extension System register, see *SVE* on page A1-75.
* b. GIC System register, see *About the GIC System registers on page D11-2671* As that subsection describes, each ICV_* register uses the same encoding as the corresponding ICC_* register.
* c. RAS Extension System registers, see *The Reliability, Availability, and Serviceability (RAS) Extension on page A1-74.*
* e. Performance Monitors Extension System register, see *Performance Monitors registers on page D12-3299.*
* f. Required if the highest implemented Exception level can use both AArch32 and AArch64. If the highest implemented Exception level can use only AArch64 then it is IMPLEMENTATION DEFINED whether this register is implemented.
* g. Generic Timer System register, see *Generic Timer registers on page D12-3441.*
* h. When ARMv8.3-CCIDX is implemented, CCSIDR_EL1 is a 64-bit register. Otherwise, it is a 32-bit register.
* i. CCSIDR2_EL1 is implemented only when ARMv8.3-CCIDX is implemented.
* j. When AArch32 is not implemented, it is IMPLEMENTATION DEFINED whether CCSIDR2_EL1 is UNDEFINED or UNKNOWN.
* k. Activity Monitors System register, see *Activity Monitors registers on page D12-3343.*
* l. Debug register in the op0==3 encoding space, see *Debug registers on page D12-3210.*
* m. Defined to allow access from AArch64 state to registers that are only used in AArch32 state.
About the GIC System registers

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- **ICC_**: GIC physical CPU interface System registers.
- **ICH_**: GIC virtual interface control System registers.
- **ICV_**: GIC Virtual CPU interface System registers.

Note: These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

When implemented, the GIC System registers form part of an ARM processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

As Table D11-2 on page D11-2660 shows, the ICV_* registers have the same \{op0, op1, CRn, CRm, op2\} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).

D11.3.2 Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0==0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 12 | 11 | 8 | 7 | 5 | 4 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 1  | 1  | 0  | 0  | 0  | 1  | 1  | CRm| 1  | 1  | x  | 1  | 1  | Rt |
| op0| CRn|
```

The value of L defines the access type and the use of Rt as follows:

- **0**: Write the value in Rt to the IMPLEMENTATION DEFINED register.
- **1**: Read the value of the IMPLEMENTATION DEFINED register to Rt.

For more information about these encodings see S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers on page D12-3071. As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using MRS and MSR instructions, see:

- **MRS** on page C6-1024.
- **MSR (immediate)** on page C6-1025.
- **MSR (register)** on page C6-1027.

See also Reserved encodings for IMPLEMENTATION DEFINED registers.

The ARM architecture guarantees not to define any register name prefixed with IMP_ as part of the standard ARM architecture.

Note: ARM strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with IMP_ and postfixed with _ELx, where appropriate.

Chapter D12
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

• *About the AArch64 System registers* on page D12-2674.
• *General system control registers* on page D12-2683.
• *Debug registers* on page D12-3210.
• *Performance Monitors registers* on page D12-3299.
• *Activity Monitors registers* on page D12-3343.
• *Statistical Profiling Extension registers* on page D12-3368.
• *RAS registers* on page D12-3404.
• *Generic Timer registers* on page D12-3441.
D12 AArch64 System Register Descriptions

D12.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

• General information about the AArch64 System registers.
• Fixed values in the System register descriptions.
• General behavior of accesses to the AArch64 System registers.
• Principles of the ID scheme for fields in ID registers on page D12-2680.

D12.1.1 General information about the AArch64 System registers

The structure of the System register descriptions has changed from that used in ARM® Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile, Issue A.3 and earlier:

• Information about the accessibility of the register from different Exception levels is given in the Accessibility section, that is the last but one section of a register description.
• Information about the traps and enables that apply to the register is given in the Traps and Enables section, that is the last section of a register description.

The information in these sections can depend on:
• The mnemonic that is used to access the register.
• The value of one or more of the controls {E2H, TGE, NS}.

These controls are:
• HCR_EL2.{E2H, TGE} fields.
• SCR_EL3.NS field.

Note

These changes mean that the register descriptions can address:
— Cases where a single register is accessible using more than one mnemonic, in different contexts, and that the accessibility can depend on the mnemonic that is used and the context in which it is used.
— Cases where a single mnemonic can address different registers, depending on the context, and that the accessibility can also depend on the context.

These changes are needed to describe System register behaviors associated with the Virtualization Host Extension described in Virtualization Host Extensions on page D5-2486. However, they also improve the representation of many ARMv8.0 register descriptions.

• This change to the structure of System register descriptions does not apply to the description of memory-mapped registers such as those described in Chapter H9 External Debug Register Descriptions.

D12.1.2 Fixed values in the System register descriptions

See Fixed values in AArch64 instruction and System register descriptions on page C2-165. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

D12.1.3 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

• Reset behavior of AArch64 System registers on page D12-2675.
• Synchronization requirements for AArch64 System registers on page D12-2675.
Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.

- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.

- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.

- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.

- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- PE state on reset to AArch64 state on page D1-2167.
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and PE state on reset to AArch64 state on page D1-2167 summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

Note

When the PE resets into an Exception level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.

Pseudocode description of resetting System registers

The AArch64.ResetSystemRegisters() pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and PE state on reset to AArch64 state on page D1-2167.

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent Context synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context synchronization event. For example, where a memory access is used to communicate a read of such a...
counter, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Direct writes using the instructions in Table D11-2 on page D11-2660 require synchronization before software can rely on the effects of changes to the System registers to affect instructions appearing in program order after the direct write to the System register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

• All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
• All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
• Any System register access that an ARM Architecture Specification or equivalent specification defines as not requiring synchronization.

Explicit synchronization occurs as a result of a Context synchronization event, which is one of the following events:

• Execution of an ISB instruction.
• Exception entry.
• Exception return.
• Execution of a DCPS instruction in Debug state.
• Execution of a DRPS instruction in Debug state.
• Exit from Debug state.

Note
The ISB and exception entry events are applicable both in Debug state and in Non-debug state.

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

Note
This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of System registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

• ISR_EL1.

• The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TV_AL_EL0, CNTV_TV_AL_EL0, CNTHP_TV_AL_EL2, and CNTPS_TV_AL_EL1.

• DBGCLAIMCLR_EL1.

• The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<\n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.

• The Debug Communications Channel registers, that is, DBGDTRRX_EL0, DBGDTR_EL0, and MDCCSR_EL0.

All other direct reads of System registers can occur in any order if synchronization has not been performed.
Table D12-1 describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

**Notes**

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D12-1, are defined as follows:

**Direct read**

Where software uses a System register access instruction to read the register, see both:

- Instructions for accessing debug System registers on page D11-2657.
- Instructions for accessing non-debug System registers on page D11-2659.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

**Direct write**

Where software uses a System register access instruction to write to the register, see both:

- Instructions for accessing debug System registers on page D11-2657.
- Instructions for accessing non-debug System registers on page D11-2659.
Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

**Indirect read** Where an instruction uses a System register to establish operating conditions for the instruction, for example, the TTBR_ELx address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

**Indirect write** Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

---

**Note**

Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

---

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in Table D12-2 on page D12-2679, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.
In addition to the requirements shown in Table D12-2:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - OSLAR_EL1. OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.
  - EDLAR, if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

  **Note**

  This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table D12-2 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.

  For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a \textit{Context synchronization event}. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

  Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See \textit{DCC and ITR access in Debug state} on page H4-6496.

  **Note**

  - The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.

  - Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
• While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

D12.1.4 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of ID registers that are characterized as comprising a set of 4-bit ID fields. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. ID registers to which this scheme applies on page D12-2681 identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note
• The ID fields described here are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

• ID fields that do not follow this scheme include the ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, see Alternative ID scheme used for the Performance Monitors Extension version on page D12-2682.

• The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section. The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {    // do something that relies on the value of the feature}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

• The field holds a signed value.
• The field value 0xF indicates that the feature is not implemented.
• The field value 0x0 indicates that the feature is implemented.
• Software that depends on the feature can use the test:

```
if value >= 0 { // Software features that depend on the presence of the hardware feature}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a fractional field that both:

• Is referred to in the definition of the original field.
• Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example D12-1 on page D12-2681 shows the use of such a field.
Example D12-1 Example of the use of a fractional field

For a field describing some class of functionality:

• The value 0x1 was defined as indicating that item A is present.
• The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

• Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
• Software that depends on the test if (value >= 0x1) can rely on feature A being present.
• If new software needs to check only that features A and B are present, then it can test:
  if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) { // Software features that depend on A and B only }

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

• The AArch64 views of the AArch32 feature ID registers given by:
  — The AArch32 Auxiliary Feature register ID_AFR0_EL1.
  — The AArch32 Processor Feature registers ID_PFR0_EL1 and ID_PFR1_EL1.
  — The AArch32 Debug Feature register ID_DFR0_EL1.
  — The AArch32 Memory Model Feature registers ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1.
  — The AArch32 Instruction Set Attribute registers ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.
  — The AArch32 Media and VFP Feature registers MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
  • The AArch64 Auxiliary Feature registers ID_AA64AFR0_EL1 and ID_AA64AFR1_EL1.
  • The AArch64 Processor Feature registers ID_AA64PFR0_EL1 and ID_AA64PFR1_EL1.
  • The AArch64 Debug Feature registers ID_AA64DFR0_EL1 and ID_AA64DFR1_EL1.
  • The AArch64 Memory Model Feature registers ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, and ID_AA64MMFR2_EL1.
  • The AArch64 Instruction Set Attribute registers ID_AA64ISAR0_EL1 and ID_AA64ISAR1_EL1.

AArch32 System registers

• The AArch32 Auxiliary Feature register ID_AFR0.
• The AArch32 Processor Feature registers ID_PFR0 and ID_PFR1.
• The AArch32 Debug Feature register ID_DFR0.
• The AArch32 Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.
• The AArch32 Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
• The AArch32 Media and FP Feature registers MVFR0, MVFR1, and MVFR2.

Memory-mapped registers
• The External Debug Processor Feature register EDPFR.
• The External Debug Feature register EDDFR.

Alternative ID scheme used for the Performance Monitors Extension version

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:
• The value $0xF$ indicates that the ARM-architected Performance Monitors Extension is not implemented.
• If the field value is not $0xF$ the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the ARM Performance Monitors Extension must be written in the form:

```
if (value != 0xF and value >= number) { // do something that relies on version 'number' of the feature }
```

For these fields, ARM deprecates use of the value $0xF$ in new implementations.
D12.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.
D12.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

--- Note ---

ARM recommends the contents of this register have no effect on the PE when HCR_EL2.{E2H, TGE} is {1, 1}, and instead the configuration and control fields are provided by the ACTLR_EL2 register. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

**Configurations**

AArch64 System register ACTLR_EL1[31:0] is architecturally mapped to AArch32 System register ACTLR[31:0].

AArch64 System register ACTLR_EL1[63:32] is architecturally mapped to AArch32 System register ACTLR2[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ACTLR_EL1 is a 64-bit register.

**Field descriptions**

The ACTLR_EL1 bit assignments are:

![Field assignments diagram]

**Implementation Defined, bits [63:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the ACTLR_EL1**

This register can be written using MSR (register) with the following syntax:

\[ \text{MSR } \langle \text{systemreg} \rangle, \langle Xt \rangle \]

This register can be read using MRS with the following syntax:

\[ \text{MRS } \langle Xt \rangle, \langle \text{systemreg} \rangle \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTLR_EL1</td>
<td>11</td>
<td>0001</td>
<td>000</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3_NS == 0 &amp;&amp; SCR_EL3_EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>(HCR_EL2_NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2_NV == 1 &amp;&amp; HCR_EL2_NV2 == 1 &amp;&amp; HCR_EL2_TGE == 0 &amp;&amp; (SCR_EL3_NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2_TGE == 1 &amp;&amp; (SCR_EL3_NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3_NS == 1 || SCR_EL3_EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TACR == 1, then accesses at EL1 are trapped to EL2.
— If (SCR_EL3_NS == 1 || SCR_EL3_EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TACR == 1, then accesses at EL1 are trapped to EL2.
D12.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

--- **Note** ---

ARM recommends the contents of this register are updated to apply to EL0 when HCR_EL2.\{E2H, TGE\} is \{1, 1\}, gaining configuration and control fields from the ACTLR_EL1. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

**Configurations**

AArch64 System register ACTLR_EL2[31:0] is architecturally mapped to AArch32 System register HACTLR[31:0].

AArch64 System register ACTLR_EL2[63:32] is architecturally mapped to AArch32 System register HACTLR2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

ACTLR_EL2 is a 64-bit register.

**Field descriptions**

The ACTLR_EL2 bit assignments are:

![Implementation Defined](image)

IMPLEMENTATION DEFINED, bits [63:0]  

IMPLEMENTATION DEFINED.  

This field resets to an architecturally UNKNOWN value.

**Accessing the ACTLR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>

<td>11</td>
<td>0001</td>
<td>100</td>
<td>001</td>
<td>0000</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191](#). Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 1 & HCR_EL2.TGE == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.3 ACTLR_EL3, Auxiliary Control Register (EL3)

The ACTLR_EL3 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ACTLR_EL3 is a 64-bit register.

**Field descriptions**

The ACTLR_EL3 bit assignments are:

```
63          0
 IMPLEMENTATION DEFINED

IMPLEMENTATION DEFINED, bits [63:0]
 IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.
```

**Accessing the ACTLR_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTLR_EL3</td>
<td>11</td>
<td>0001</td>
<td>110</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>

<tr>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.4 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

**Configurations**

AArch64 System register AFSR0_EL1[31:0] is architecturally mapped to AArch32 System register ADFSR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR0_EL1 is a 64-bit register.

**Field descriptions**

The AFSR0_EL1 bit assignments are:

![Bit Assignments Diagram]

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the AFSR0_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>

</tbody>
</table>

When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic AFSR0_EL1 or AFSR0_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If IsUsingAccessor(AFSR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(AFSR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && IsUsingAccessor(AFSR0_EL12) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(AFSR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.
D12.2.5 AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

**Configurations**

AArch64 System register AFSR0_EL2[31:0] is architecturally mapped to AArch32 System register HADFSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR0_EL2 is a 64-bit register.

**Field descriptions**

The AFSR0_EL2 bit assignments are:

![AFSR0_EL2 Bit Assignment Diagram]

**Accessing the AFSR0_EL2**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFSR0_EL2</td>
<td>11</td>
<td>0101</td>
<td>100</td>
<td>000</td>
<td>0001</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>11</td>
<td>0101</td>
<td>000</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>EL1</td>
</tr>
<tr>
<td>AFSR0_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
</tr>
<tr>
<td>AFSR0_EL2</td>
<td>HCR_EL2.TGE == 0 &amp; SCR_EL3.NS == 1</td>
</tr>
<tr>
<td>AFSR0_EL2</td>
<td>HCR_EL2.TGE == 1 &amp; SCR_EL3.NS == 1</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; SCR_EL3.NS == 1</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; SCR_EL3.NS == 1</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 0 &amp; SCR_EL3.NS == 1</td>
</tr>
<tr>
<td>AFSR0_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; SCR_EL3.NS == 1</td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic AFSR0_EL2 or AFSR0_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to AFSR0_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.6  AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)

The AFSR0_EL3 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR0_EL3 is a 64-bit register.

**Field descriptions**

The AFSR0_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED, bits [63:0]</td>
<td>IMPLEMENTATION DEFINED. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the AFSR0_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFSR0_EL3</td>
<td>11</td>
<td>0101</td>
<td>110</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>EL0</th>
<th>EL1</th>

<td>n/a</td>
</tr>
</tbody>
</table>
D12.2.7 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

**Configurations**

AArch64 System register AFSR1_EL1[31:0] is architecturally mapped to AArch32 System register AIFSR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR1_EL1 is a 64-bit register.

**Field descriptions**

The AFSR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the AFSR1_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If IsUsingAccessor(AFSR1_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If IsUsingAccessor(AFSR1_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && IsUsingAccessor(AFSR1_EL12) && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && IsUsingAccessor(AFSR1_EL1) && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(AFSR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && IsUsingAccessor(AFSR1_EL1) && HCR_EL2.TVM == 1, then access at EL1 are trapped to EL2.
D12.2.8 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Configurations

AArch64 System register AFSR1_EL2[31:0] is architecturally mapped to AArch32 System register HAIFSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR1_EL2 is a 64-bit register.

Field descriptions

The AFSR1_EL2 bit assignments are:

63
   IMPLEMENTATION DEFINED
   IMPLEMENTATION DEFINED, bits [63:0]
   IMPLEMENTATION DEFINED.
   This field resets to an architecturally UNKNOWN value.

Accessing the AFSR1_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFSR1_EL2</td>
<td>11</td>
<td>0101</td>
<td>100</td>
<td>001</td>
<td>0001</td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td>11</td>
<td>0101</td>
<td>000</td>
<td>001</td>
<td>0001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>AFSR1_EL2</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL2</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL2</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td></td>
</tr>
<tr>
<td>AFSR1_EL1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic AFSR1_EL2 or AFSR1_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to AFSR1_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.9 AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)

The AFSR1_EL3 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR1_EL3 is a 64-bit register.

**Field descriptions**

The AFSR1_EL3 bit assignments are:

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the AFSR1_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFSR1_EL3</td>
<td>11</td>
<td>0101</td>
<td>110</td>
<td>001</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
D12.2.10  AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED identification information. The value of this register must be interpreted in conjunction with the value of MIDR_EL1.

**Configurations**

AArch64 System register AIDR_EL1[31:0] is architecturally mapped to AArch32 System register AIDR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AIDR_EL1 is a 64-bit register.

**Field descriptions**

The AIDR_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

**Accessing the AIDR_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>001</td>
<td>11</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If $(SCR_{EL3}.NS == 1 \lor SCR_{EL3}.EEL2 == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& HCR_{EL2}.E2H == 0 \&\& HCR_{EL2}.TID1 == 1$, then read accesses at EL1 are trapped to EL2.

— If $(SCR_{EL3}.NS == 1 \lor SCR_{EL3}.EEL2 == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& HCR_{EL2}.E2H == 1 \&\& HCR_{EL2}.TID1 == 1$, then read accesses at EL1 are trapped to EL2.
### D12.2.11 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

**Configurations**

AArch64 System register AMAIR_EL1[31:0] is architecturally mapped to AArch32 System register AMAIR0[31:0].

AArch64 System register AMAIR_EL1[63:32] is architecturally mapped to AArch32 System register AMAIR1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR_EL1 is a 64-bit register.

**Field descriptions**

The AMAIR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>IMPLEMENTATION DEFINED, bits [63:0]</td>
</tr>
<tr>
<td>0</td>
<td>IMPLEMENTATION DEFINED. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

AMAIR_EL1 is permitted to be cached in a TLB.

**Accessing the AMAIR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAIR_EL1</td>
<td>11</td>
<td>1010</td>
<td>000</td>
<td>000</td>
<td>0011</td>
</tr>
<tr>
<td>AMAIR_EL12</td>
<td>11</td>
<td>1010</td>
<td>101</td>
<td>000</td>
<td>0011</td>

<tr>
<td><strong>AMAIR_EL12</strong></td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 0 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td><strong>AMAIR_EL12</strong></td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td><strong>AMAIR_EL12</strong></td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td><strong>AMAIR_EL12</strong></td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 0 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td><strong>AMAIR_EL12</strong></td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When **HCR_EL2.E2H** is 1, without explicit synchronization, access from EL3 using the mnemonic **AMAIR_EL1** or **AMAIR_EL12** are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If IsUsingAccesser(AMAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccesser(AMAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

- If IsUsingAccesser(AMAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then write accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccesser(AMAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

- If IsUsingAccesser(AMAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccesser(AMAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

- If IsUsingAccesser(AMAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccesser(AMAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.
D12.2.12 AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL2.

Configurations

AArch64 System register AMAIR_EL2[31:0] is architecturally mapped to AArch32 System register HAMAIR0[31:0].

AArch64 System register AMAIR_EL2[63:32] is architecturally mapped to AArch32 System register HAMAIR1[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR_EL2 is a 64-bit register.

Field descriptions

The AMAIR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

AMAIR_EL2 is permitted to be cached in a TLB.

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

Accessing the AMAIR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAIR_EL2</td>
<td>11</td>
<td>1010</td>
<td>100</td>
<td>000</td>
<td>0011</td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>11</td>
<td>1010</td>
<td>000</td>
<td>000</td>
<td>0011</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>AMAIR_EL2</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
</tr>
<tr>
<td>AMAIR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>AMAIR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic AMAIR_EL2 or AMAIR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to AMAIR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.13 AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)

The AMAIR_EL3 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR_EL3 is a 64-bit register.

**Field descriptions**

The AMAIR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

AMAIR_EL3 is permitted to be cached in a TLB.

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the AMAIR_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAIR_EL3</td>
<td>11</td>
<td>1010</td>

<td></td>
</tr>
</tbody>
</table>
D12.2.14 APDAKeyHi_EL1, Pointer Authentication Key A for Data (bits[127:64])

The APDAKeyHi_EL1 characteristics are:

**Purpose**

Holds bits[127:64] of key A used for authentication of data pointer values.

--- Note ---

The term APDAKey_EL1 is used to describe the concatenation of APDAKeyHi_EL1: APDAKeyLo_EL1.

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APDAKeyHi_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APDAKeyHi_EL1 is a 64-bit register.

**Field descriptions**

The APDAKeyHi_EL1 bit assignments are:

64 bit value, bits[127:64] of the 128 bit pointer authentication key value

**Bits [63:0]**

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

This field resets to an architecturally UNKNOWN value.

**Accessing the APDAKeyHi_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APDAKeyHi_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.15  APDAKeyLo_EL1, Pointer Authentication Key A for Data (bits[63:0])

The APDAKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key A used for authentication of data pointer values.

**Note**

The term APDAKey_EL1 is used to describe the concatenation of APDAKeyHi_EL1: APDAKeyLo_EL1.

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APDAKeyLo_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APDAKeyLo_EL1 is a 64-bit register.

**Field descriptions**

The APDAKeyLo_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>64 bit value, bits[63:0] of the 128 bit pointer authentication key value</th>
</tr>
</thead>
</table>

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

This field resets to an architecturally UNKNOWN value.

**Accessing the APDAKeyLo_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APDAKeyLo_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>
**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.16 APDBKeyHi_EL1, Pointer Authentication Key B for Data (bits[127:64])

The APDBKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key B used for authentication of data pointer values.

Note

The term APDBKey_EL1 is used to describe the concatenation of APDBKeyHi_EL1:

APDBKeyLo_EL1.

Configurations

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APDBKeyHi_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

APDBKeyHi_EL1 is a 64-bit register.

Field descriptions

The APDBKeyHi_EL1 bit assignments are:

64 bit value, bits[127:64] of the 128 bit pointer authentication key value

Bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

This field resets to an architecturally UNKNOWN value.

Accessing the APDBKeyHi_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APDBKeyHi_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>011</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -</td>
</tr>
<tr>
<td></td>
<td>EL1: RW</td>
</tr>
<tr>
<td></td>
<td>EL2: n/a</td>
</tr>
<tr>
<td></td>
<td>EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL1: RW</td>
</tr>
<tr>
<td></td>
<td>EL2: RW</td>
</tr>
<tr>
<td></td>
<td>EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL1: n/a</td>
</tr>
<tr>
<td></td>
<td>EL2: RW</td>
</tr>
<tr>
<td></td>
<td>EL3: RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If \((\text{SCR\_EL3.NS} == 1 \land \text{SCR\_EL3.EEL2} == 1) \land \text{IsUsingAAArch64(EL2)} \land \text{HCR\_EL2.APK} == 0\), then accesses at EL1 are trapped to EL2.
— If \(\text{IsUsingAAArch64(EL3)} \land \text{SCR\_EL3.APK} == 0\), then accesses at EL1 or EL2 are trapped to EL3.
D12.2.17 APDBKeyLo_EL1, Pointer Authentication Key B for Data (bits[63:0])

The APDBKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key B used for authentication of data pointer values.

--- Note ---

The term APDBKey_EL1 is used to describe the concatenation of APDBKeyHi_EL1: APDBKeyLo_EL1.

---

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APDBKeyLo_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APDBKeyLo_EL1 is a 64-bit register.

**Field descriptions**

The APDBKeyLo_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>64 bit value, bits[63:0] of the 128 bit pointer authentication key value</td>
</tr>
<tr>
<td>0</td>
<td>64 bit value, bits[63:0] of the 128 bit pointer authentication key value. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the APDBKeyLo_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APDBKeyLo_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>010</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td></td>
<td>-  RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.18 APGAKeyHi_EL1, Pointer Authentication Key A for Code (bits[127:64])

The APGAKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key used for generic pointer authentication code.

Note

The term APGAKey_EL1 is used to describe the concatenation of APGAKeyHi_EL1: APGAKeyLo_EL1.

Configurations

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APGAKeyHi_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

APGAKeyHi_EL1 is a 64-bit register.

Field descriptions

The APGAKeyHi_EL1 bit assignments are:

64 bit value, bits[127:64] of the 128 bit pointer authentication key value

Bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

This field resets to an architecturally UNKNOWN value.

Accessing the APGAKeyHi_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APGAKeyHi_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.19 APGAKeyLo_EL1, Pointer Authentication Key A for Code (bits[63:0])

The APGAKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key used for generic pointer authentication code.

--- **Note** ---

The term APGAKey_EL1 is used to describe the concatenation of APGAKeyHi_EL1: APGAKeyLo_EL1.

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APGAKeyLo_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APGAKeyLo_EL1 is a 64-bit register.

**Field descriptions**

The APGAKeyLo_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>64 bit value, bits[63:0] of the 128 bit pointer authentication key value</td>
</tr>
<tr>
<td>62</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the APGAKeyLo_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>APGAKeyLo_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>000</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.20 APIAKeyHi_EL1, Pointer Authentication Key A for Instruction (bits[127:64])

The APIAKeyHi_EL1 characteristics are:

**Purpose**
Holds bits[127:64] of key A used for authentication of instruction pointer values.

--- Note ---
The term APIAKey_EL1 is used to describe the concatenation of APIAKeyHi_EL1: APIAKeyLo_EL1.

**Configurations**
This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APIAKeyHi_EL1 are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
APIAKeyHi_EL1 is a 64-bit register.

**Field descriptions**
The APIAKeyHi_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>64 bit value, bits[127:64] of the 128 bit pointer authentication key value</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the APIAKeyHi_EL1**
This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>

<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW, EL1: n/a, EL2: RW, EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.21 APIAKeyLo_EL1, Pointer Authentication Key A for Instruction (bits[63:0])

The APIAKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key A used for authentication of instruction pointer values.

--- **Note** ---

The term APIAKey_EL1 is used to describe the concatenation of APIAKeyHi_EL1: APIAKeyLo_EL1.

---

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APIAKeyLo_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APIAKeyLo_EL1 is a 64-bit register.

**Field descriptions**

The APIAKeyLo_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>64 bit value, bits[63:0] of the 128 bit pointer authentication key value</td>
<td>Architecturally UNKNOWN</td>
</tr>
</tbody>
</table>

**Accessing the APIAKeyLo_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>

<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.22 APIBKeyHi_EL1, Pointer Authentication Key B for Instruction (bits[127:64])

The APIBKeyHi_EL1 characteristics are:

**Purpose**

Holds bits[127:64] of key B used for authentication of instruction pointer values.

--- **Note** ---

The term APIBKey_EL1 is used to describe the concatenation of APIBKeyHi_EL1: APIBKeyLo_EL1.

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APIBKeyHi_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APIBKeyHi_EL1 is a 64-bit register.

**Field descriptions**

The APIBKeyHi_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits {63:0}</th>
</tr>
</thead>
<tbody>
<tr>
<td>64 bit value, bits[127:64] of the 128 bit pointer authentication key value</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the APIBKeyHi_EL1**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>

<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
### D12.2.23 APIBKeyLo_EL1, Pointer Authentication Key B for Instruction (bits[63:0])

The APIBKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key B used for authentication of instruction pointer values.

---

**Note**

The term APIBKey_EL1 is used to describe the concatenation of APIBKeyHi_EL1:

APIBKeyLo_EL1.

---

**Configurations**

This register is present only when ARMv8.3-PAuth is implemented. Otherwise, direct accesses to APIBKeyLo_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

APIBKeyLo_EL1 is a 64-bit register.

**Field descriptions**

The APIBKeyLo_EL1 bit assignments are:

| Bit 63 | Bit 62 | Bit 61 | Bit 60 | Bit 59 | Bit 58 | Bit 57 | Bit 56 | Bit 55 | Bit 54 | Bit 53 | Bit 52 | Bit 51 | Bit 50 | Bit 49 | Bit 48 | Bit 47 | Bit 46 | Bit 45 | Bit 44 | Bit 43 | Bit 42 | Bit 41 | Bit 40 | Bit 39 | Bit 38 | Bit 37 | Bit 36 | Bit 35 | Bit 34 | Bit 33 | Bit 32 | Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |

<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.APK == 0, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && SCR_EL3.APK == 0, then accesses at EL1 or EL2 are trapped to EL3.
### D12.2.24 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

**Purpose**

When ARMv8.3-CCIDX is implemented, provides the information about the architecture of the currently selected cache from bits[63:32] of CCSIDR_EL1.

When ARMv8.3-CCIDX is not implemented, this register is not implemented.

**Configurations**

AArch64 System register CCSIDR2_EL1[31:0] is architecturally mapped to AArch32 System register CCSIDR2[31:0].

This register is present only when ARMv8.3-CCIDX is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

If AArch32 is not implemented, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

The implementation includes one CCSIDR2_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CCSIDR2_EL1 is a 64-bit register.

**Field descriptions**

The CCSIDR2_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>24</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>23</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>22</td>
<td>NumSets</td>
</tr>
<tr>
<td>21</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td></td>
</tr>
<tr>
<td>19</td>
<td></td>
</tr>
<tr>
<td>18</td>
<td></td>
</tr>
<tr>
<td>17</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
<tr>
<td>15</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td></td>
</tr>
<tr>
<td>13</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:24]**

Reserved, RES0.

**NumSets, bits [23:0]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Accessing the CCSIDR2_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCSIDR2_EL1</td>
<td>0000</td>
<td>11</td>
<td>001</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a; EL1: RO; EL2: RO; EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.25 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache.

**Configurations**

AArch64 System register CCSIDR_EL1[31:0] is architecturally mapped to AArch32 System register CCSIDR[31:0].

AArch64 System register CCSIDR_EL1 bits [63:32] are architecturally mapped to AArch32 System register CCSIDR2.

The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CCSIDR_EL1 is a 64-bit register.

**Field descriptions**

The CCSIDR_EL1 bit assignments are:

*When ARMv8.3-CCIDX is implemented:*

\[
\begin{array}{cccccccc}
63 & 62 & 61 & 60 & 59 & 58 & 57 & 56 \\
| RES0 | NumSets | RES0 | Associativity | LineSize |
\end{array}
\]

**Note**

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

**Bits [63:56]**

Reserved, RES0.

**NumSets, bits [55:32]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Bits [31:24]**

Reserved, RES0.

**Associativity, bits [23:3]**

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

**LineSize, bits [2:0]**

(Log₂(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: Log₂(16) = 4, LineSize entry = 0. This is the minimum line length.
• For a line length of 32 bytes: \( \log_2(32) = 5 \), LineSize entry = 1.

**Otherwise:**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>13</th>
<th>12</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNKNOWN</td>
<td>NumSets</td>
<td></td>
<td>Associativity</td>
<td>LineSize</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**
Reserved, RES0.

**UNKNOWN, Bits [31:28]**
Reserved, UNKNOWN.

**NumSets, bits [27:13]**
(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Associativity, bits [12:3]**
(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

**LineSize, bits [2:0]**
(Log2(Number of bytes in cache line)) - 4. For example:
• For a line length of 16 bytes: \( \log_2(16) = 4 \), LineSize entry = 0. This is the minimum line length.
• For a line length of 32 bytes: \( \log_2(32) = 5 \), LineSize entry = 1.

**Accessing the CCSIDR_EL1**
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCSIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>001</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RO; EL1: n/a; EL2: RO; EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
If CSSEL_EL1.Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.26 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

**Purpose**

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architectured cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Configurations**

AArch64 System register CLIDR_EL1[31:0] is architecturally mapped to AArch32 System register CLIDR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CLIDR_EL1 is a 64-bit register.

**Field descriptions**

The CLIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:33]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 33 RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>32 30 ICB</td>
<td>Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.</td>
</tr>
<tr>
<td>29 27 LoUU</td>
<td>Level of Unification Uniprocessor for the cache hierarchy.</td>
</tr>
<tr>
<td>26 24 LoC</td>
<td>Level of Coherence for the cache hierarchy.</td>
</tr>
<tr>
<td>23 21 LoUIS</td>
<td>Level of Unification Inner Shareable for the cache hierarchy.</td>
</tr>
<tr>
<td>20 18 Ctype7</td>
<td></td>
</tr>
<tr>
<td>17 15 Ctype6</td>
<td></td>
</tr>
<tr>
<td>14 12 Ctype5</td>
<td></td>
</tr>
<tr>
<td>11 09 Ctype4</td>
<td></td>
</tr>
<tr>
<td>08 06 Ctype3</td>
<td></td>
</tr>
<tr>
<td>05 03 Ctype2</td>
<td></td>
</tr>
<tr>
<td>02 00 Ctype1</td>
<td></td>
</tr>
</tbody>
</table>

**ICB, bits [32:30]**

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

- 0b000: Not disclosed by this mechanism.
- 0b001: L1 cache is the highest Inner Cacheable level.
- 0b010: L2 cache is the highest Inner Cacheable level.
- 0b011: L3 cache is the highest Inner Cacheable level.
- 0b100: L4 cache is the highest Inner Cacheable level.
- 0b101: L5 cache is the highest Inner Cacheable level.
- 0b110: L6 cache is the highest Inner Cacheable level.
- 0b111: L7 cache is the highest Inner Cacheable level.

**LoUU, bits [29:27]**

Level of Unification Uniprocessor for the cache hierarchy.

**LoC, bits [26:24]**

Level of Coherence for the cache hierarchy.

**LoUIS, bits [23:21]**

Level of Unification Inner Shareable for the cache hierarchy.
Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the
architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to
a maximum of seven levels of cache hierarchy. Possible values of each field are:

- 0b000 No cache.
- 0b001 Instruction cache only.
- 0b010 Data cache only.
- 0b011 Separate instruction and data caches.
- 0b100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no
 caches that can be managed using the architected cache maintenance instructions that operate by
set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type
field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>001</td>
<td>001</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RO, EL1: n/a, EL2: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for
exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H ==
  0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H ==
  1 && HCR_EL2.TGE == 0 && HCR_EL2.TID2 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.27 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

**Purpose**

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

This register is used:

- In ARMv8.0.
- When ARMv8.1-VHE is implemented and HCR_EL2.E2H is 0.

--- Note ---

When ARMv8.1-VHE is implemented and HCR_EL2.E2H is set to 1, CONTEXTIDR_EL2 is used.

**Configurations**

AArch64 System register CONTEXTIDR_EL1[31:0] is architecturally mapped to AArch32 System register CONTEXTIDR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CONTEXTIDR_EL1 is a 64-bit register.

**Field descriptions**

The CONTEXTIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>PROCID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**PROCID, bits [31:0]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

--- Note ---

In AArch32 state, when TTBCR.EAE is set to 0, CONTEXTIDR.ASID holds the ASID.

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either TTBR0_EL1 or TTBR1_EL1 holds the ASID.

This field resets to an architecturally UNKNOWN value.

**Accessing the CONTEXTIDR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>11</td>
<td>1101</td>
<td>000</td>
<td>001</td>
<td>0000</td>
</tr>
<tr>
<td>CONTEXTIDR_EL12</td>
<td>11</td>
<td>1101</td>
<td>101</td>
<td>001</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW, EL1: n/a, EL2: RW, EL3: RW</td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
</tbody>
</table>
When \( \text{HCR\_EL2.E2H} \) is 1, without explicit synchronization, access from EL3 using the mnemonic CONTEXTIDR\_EL1 or CONTEXTIDR\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>( \text{HCR_EL2.TGE == 1 &amp;&amp;} ) ( \text{HCR_EL2.E2H == 1 &amp;&amp;} ) ( \text{(SCR_EL3.NS == 1 &amp;&amp;} ) ( \text{SCR_EL3.EEL2 == 1)} )</td>
<td>-</td>
</tr>
<tr>
<td>CONTEXTIDR_EL12</td>
<td>( \text{SCR_EL3.NS == 0 &amp;&amp;} ) ( \text{SCR_EL3.EEL2 == 0) )</td>
<td>-</td>
</tr>
<tr>
<td>CONTEXTIDR_EL12</td>
<td>( \text{(HCR_EL2.NV == 0 &amp;&amp;} ) ( \text{HCR_EL2.NV1 == 1 &amp;&amp;} ) ( \text{HCR_EL2.NV2 == 0) &amp;&amp;} ) ( \text{HCR_EL2.TGE == 0 &amp;&amp;} ) ( \text{HCR_EL2.E2H == 0 &amp;&amp;} ) ( \text{(SCR_EL3.NS == 1 &amp;&amp;} ) ( \text{SCR_EL3.EEL2 == 1)} )</td>
<td>-</td>
</tr>
<tr>
<td>CONTEXTIDR_EL12</td>
<td>( \text{HCR_EL2.TGE == 1 &amp;&amp;} ) ( \text{HCR_EL2.E2H == 0 &amp;&amp;} ) ( \text{(SCR_EL3.NS == 1 &amp;&amp;} ) ( \text{SCR_EL3.EEL2 == 1)} )</td>

<td>-</td>
</tr>
<tr>
<td>CONTEXTIDR_EL12</td>
<td>( \text{HCR_EL2.TGE == 1 &amp;&amp;} ) ( \text{HCR_EL2.E2H == 1 &amp;&amp;} ) ( \text{(SCR_EL3.NS == 1 &amp;&amp;} ) ( \text{SCR_EL3.EEL2 == 1)} )</td>
<td>-</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If IsUsingAccessor(CONTEXTIDR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(CONTEXTIDR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If IsUsingAccessor(CONTEXTIDR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(CONTEXTIDR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

- If IsUsingAccessor(CONTEXTIDR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(CONTEXTIDR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

- If IsUsingAccessor(CONTEXTIDR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && IsUsingAccessor(CONTEXTIDR_EL12) && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.28 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

**Purpose**

When ARMv8.1-VHE is implemented and HCR_EL2.E2H is set to 1, identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

--- **Note** ---

In ARMv8.0, or when ARMv8.1-VHE is implemented and HCR_EL2.E2H is 0, CONTEXTIDR_EL2 replaces CONTEXTIDR_EL1 where CONTEXTIDR_EL1 would usually be used.

---

**Configurations**

This register is present only from ARMv8.1. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

CONTEXTIDR_EL2 is a 64-bit register.

**Field descriptions**

The CONTEXTIDR_EL2 bit assignments are:

![Context ID Register Diagram]

**Bits [63:32]**

Reserved, RES0.

**PROCID, bits [31:0]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

--- **Note** ---

In AArch32 state, when TTBCR.EAE is set to 0, CONTEXTIDR.ASID holds the ASID.
In AArch64 state, CONTEXTIDR_EL2 is independent of the ASID, and for the EL2&0 translation regime either TTBR0_EL2 or TTBR1_EL2 holds the ASID.

This field resets to an architecturally UNKNOWN value.
Accessing the CONTEXTIDR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL2</td>
<td>1101</td>
<td>11</td>
<td>100</td>
<td>001</td>
<td>0000</td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>1101</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: n/a, EL2: RW, EL3: RW</td>
</tr>
<tr>
<td>CONTEXTIDR_EL2</td>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: CONTEXTIDR_EL1, EL1: CONTEXTIDR_EL1, EL2: CONTEXTIDR_EL1, EL3: CONTEXTIDR_EL1</td>
</tr>
</tbody>
</table>
When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CONTEXTIDR_EL2 or CONTEXTIDR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to CONTEXTIDR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see _Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191_. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 1 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CONTEXTIDR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.29 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

**Purpose**

Controls access to trace, SVE, Advanced SIMD and floating-point functionality.

**Configurations**

AArch64 System register CPACR_EL1[31:0] is architecturally mapped to AArch32 System register CPACR[31:0].

When HCR_EL2.{E2H, TGE} == {1, 1}, the fields in this register have no effect on execution at EL0 and EL1. In this case, the controls provided by CPTR_EL2 are used.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPACR_EL1 is a 64-bit register.

**Field descriptions**

The CPACR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Bit Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:29]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[28]</td>
<td>TTA, bit [28]</td>
</tr>
<tr>
<td>[27:22]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[21:20]</td>
<td>FPEN</td>
</tr>
<tr>
<td>[19:18]</td>
<td>ZEN</td>
</tr>
<tr>
<td>[15:0]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Bits [63:29]**

Reserved, RES0.

**TTA, bit [28]**

Traps EL0 and EL1 System register accesses to all implemented trace registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states.

0b0 This control does not cause any instructions to be trapped.

0b1 This control causes EL0 and EL1 System register accesses to all implemented trace registers to be trapped.

--- Note ---

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.TTA is 1.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not implemented, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**Bits [27:22]**

Reserved, RES0.
FPEN, bits [21:20]
Traps EL0 and EL1 accesses to the SVE, Advanced SIMD, and floating-point registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states.

0b00 This control causes any instructions at EL0 or EL1 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless they are trapped by CPACR_EL1.ZEN.

0b01 This control causes any instructions at EL0 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless they are trapped by CPACR_EL1.ZEN, but does not cause any instruction at EL1 to be trapped.

0b10 This control causes any instructions at EL0 or EL1 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless they are trapped by CPACR_EL1.ZEN.

0b11 This control does not cause any instructions to be trapped.

Writes to MVFR0, MVFR1 and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

--- Note ---
• Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
• Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.FPEN is not 0b11.

This field resets to an architecturally UNKNOWN value.

Bits [19:18]
Reserved, RES0.

ZEN, bits [17:16]

When SVE is implemented:
Traps SVE instructions and instructions that access SVE System registers at EL0 and EL1 to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

0b00 This control causes these instructions executed at EL0 or EL1 to be trapped.

0b01 This control causes these instructions executed at EL0 to be trapped, but does not cause any instruction at EL1 to be trapped.

0b10 This control causes these instructions executed at EL0 or EL1 to be trapped.

0b11 This control does not cause any instruction to be trapped.

If SVE is not implemented, this field is RES0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [15:0]
Reserved, RES0.

Accessing the CPACR_EL1
This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPACR_EL1</td>
<td>11</td>
<td>001</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
<tr>
<td>CPACR_EL12</td>
<td>11</td>
<td>0001</td>
<td>101</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td></td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `CPACR_EL1` or `CPACR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If IsUsingAccessor(CPACR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && CPTR_EL2.TCPAC == 1, then accesses at EL1 are trapped to EL2.
- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(CPACR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && CPTR_EL2.TCPAC == 1, then accesses at EL1 are trapped to EL2.
- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && IsUsingAccessor(CPACR_EL12) && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAccessor(CPACR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && CPTR_EL2.TCPAC == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAccessor(CPACR_EL1) && IsUsingAArch64(EL3) && CPTR_EL3.TCPAC == 1, then accesses at EL2 are trapped to EL3.
- If IsUsingAccessor(CPACR_EL1) && IsUsingAArch64(EL3) && CPTR_EL3.TCPAC == 1, then accesses at EL1 are trapped to EL3.
- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(CPACR_EL12) && IsUsingAArch64(EL3) && CPTR_EL3.TCPAC == 1, then accesses at EL1 are trapped to EL3.
D12.2.30 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

**Purpose**

Controls:
- Trapping to EL2 of access to CPACR, CPACR_EL1, trace functionality, and to SVE, Advanced SIMD and floating-point functionality.
- EL2 access to trace functionality, and to SVE, Advanced SIMD and floating-point functionality.

**Configurations**

AArch64 System register CPTR_EL2[31:0] is architecturally mapped to AArch32 System register HCPTR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPTR_EL2 is a 64-bit register.

**Field descriptions**

The CPTR_EL2 bit assignments are:

*When HCR_EL2.E2H == 0:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>62-32</td>

TAM, bit [30]

When AMUv1 is implemented:

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2, when EL2 is enabled in the current Security state.

0b0  Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.

0b1  Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

From ARMv8.1:

Traps System register accesses to all implemented trace registers to EL2 when it is enabled in the current Security state, from both Execution states.

0b0  This control does not cause any instructions to be trapped.

0b1  Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace register is trapped to EL2 when it is enabled in the current Security state, unless it is trapped by CPACR.TRCDIS or CPACR_EL1.TTA.

Note

The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.

EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps accesses to SVE, Advanced SIMD and floating-point functionality to EL2 when it is enabled in the current Security state, from both Execution states.

0b0  This control does not cause any instructions to be trapped.
0b1

Any attempt at EL0, EL1 or EL2, to execute an instruction that uses the registers associated with SVE, Advanced SIMD and floating-point execution is trapped to EL2 when it is enabled in the current Security state, subject to the exception prioritization rules, unless it is trapped by CPTR_EL2.TZ.

This field resets to an architecturally UNKNOWN value.

Bit [9]

Reserved, RES1.

TZ, bit [8]

*When SVE is implemented:*

Traps execution at EL2, EL1, or EL0 of SVE instructions and instructions that access SVE System registers to EL2 when it is enabled in the current Security state.

0b0

This control does not cause any instruction to be trapped.

0b1

This control causes these instructions to be trapped, subject to the exception prioritization rules.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES1.

Bits [7:0]

Reserved, RES1.

*When HCR_EL2.E2H == 1:*

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

*From ARMv8.1:*

When HCR_EL2.TGE is 0, traps EL1 accesses to CPACR_EL1 and CPACR to EL2 when it is enabled in the current Security state, from both Execution states.

0b0

This control does not cause any instructions to be trapped.

0b1

EL1 accesses to CPACR_EL1 and CPACR are trapped to EL2 when it is enabled in the current Security state.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

--- Note

CPACR_EL1 and CPACR are not accessible at EL0.

This field resets to an architecturally UNKNOWN value.
TAM, bit [30]

**When AMUv1 is implemented:**
Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2.

- **0b0**: Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.
- **0b1**: Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2, when EL2 is enabled in the current Security state.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

Bit [29]
Reserved, RES0.

TTA, bit [28]

**From ARMv8.1:**
Traps System register accesses to all implemented trace registers to EL2 when it is enabled in the current Security state, from both Execution states.

- **0b0**: This control does not cause any instructions to be trapped.
- **0b1**: Any attempt at EL0, EL1 or EL2, to execute a System register access to an implemented trace register is trapped to EL2 when it is enabled in the current Security state, unless HCR_EL2.TGE is 0 and it is trapped by CPACR.NSTRCDIS or CPACR_EL1.TTA. When HCR_EL2.TGE is 1, any attempt at EL0 or EL2 to execute a System register access to an implemented trace register is trapped to EL2 when it is enabled in the current Security state.

**Note**
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

Bits [27:22]
Reserved, RES0.
FPEN, bits [21:20]

*From ARMv8.1:*

Traps EL0, EL2 and, when \(\text{HCR}_{-}\text{EL2}.\text{TGE}\) is 0, EL1 accesses to the SVE, Advanced SIMD and floating-point registers to EL2 when it is enabled in the current Security state, from both Execution states.

- **0b00**  This control causes any instructions at EL0, EL1, or EL2 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, subject to the exception prioritization rules, unless they are trapped by \(\text{CPTR}_{-}\text{EL2}.\text{ZEN}\).
- **0b01**  When \(\text{HCR}_{-}\text{EL2}.\text{TGE}\) is 0, this control does not cause any instructions to be trapped. When \(\text{HCR}_{-}\text{EL2}.\text{TGE}\) is 1, this control causes instructions at EL0 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless they are trapped by \(\text{CPTR}_{-}\text{EL2}.\text{ZEN}\), but does not cause any instruction at EL2 to be trapped.
- **0b10**  This control causes any instructions at EL0, EL1, or EL2 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, subject to the exception prioritization rules, unless they are trapped by \(\text{CPTR}_{-}\text{EL2}.\text{ZEN}\).
- **0b11**  This control does not cause any instructions to be trapped.

 Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

---

**Note**

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of \(\text{CPTR}_{-}\text{EL2}.\text{FPEN}\) is not 0b1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [19:18]**

Reserved, RES0.

**ZEN, bits [17:16]**

*When SVE is implemented:*

Traps execution at EL2, EL1, and EL0 of SVE instructions or instructions that access SVE System registers to EL2 when it is enabled in the current Security state.

- **0b00**  This control causes execution at EL2, EL1, and EL0 of these instructions to be trapped, subject to the exception prioritization rules.
- **0b01**  When \(\text{HCR}_{-}\text{EL2}.\text{TGE}\) is 0, this control does not cause any instruction to be trapped. When \(\text{HCR}_{-}\text{EL2}.\text{TGE}\) is 1, this control causes these instructions executed at EL0 to be trapped, but does not cause any instruction at EL2 to be trapped.
- **0b10**  This control causes execution at EL2, EL1, and EL0 of these instructions to be trapped, subject to the exception prioritization rules.
- **0b11**  This control does not cause any instruction to be trapped.

This field resets to an architecturally UNKNOWN value.

Accessing the CPTR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPTR_EL2</td>
<td>11</td>
<td>0001</td>
<td>100</td>
<td>010</td>
<td>0001</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>11</td>
<td>0001</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPTR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 1 &amp; SCR_EL3.EEL2 == 1</td>
<td>-</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 1 &amp; SCR_EL3.EEL2 == 1</td>
<td>-</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 1 &amp; SCR_EL3.EEL2 == 1</td>
<td>-</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>SCR_EL3.NS == 1 &amp; SCR_EL3.EEL2 == 1</td>
<td>-</td>
</tr>
</tbody>
</table>

If an _EL1 accessor is used, refer to CPACR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If `IsUsingAArch64(EL3) && CPTR_EL3.TCPAC == 1`, then accesses at EL2 are trapped to EL3.
- If `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1`, then accesses at EL1 are trapped to EL2.
- If `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1`, then accesses at EL1 are trapped to EL2.
D12.2.31 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

**Purpose**

Controls trapping to EL3 of access to CPACR_EL1, CPTR_EL2, trace functionality and registers associated with SVE, Advanced SIMD and floating-point execution. Also controls EL3 access to trace functionality and registers associated with SVE, Advanced SIMD and floating-point execution.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPTR_EL3 is a 64-bit register.

**Field descriptions**

The CPTR_EL3 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32
  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | RES0
  | TCPAC | 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
   | RES0 | RES0 | RES0 | EZ | RES0 | RES0 | RES0 | TFP | TTA
```

**Bits [63:32]**

Reserved, RES0.

**TCPAC, bit [31]**

Traps all of the following to EL3, from both Security states and both Execution states.

- EL2 accesses to the CPTR_EL2 or HCPR
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR

When CPTR_EL3.TCPAC is:

- **0b0**: This control does not cause any instructions to be trapped.
- **0b1**: EL2 accesses to the CPTR_EL2 or HCPR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3, unless they are trapped by CPTR_EL2.TCPAC.

This field resets to an architecturally UNKNOWN value.

**TAM, bit [30]**

*When AMUv1 is implemented:*

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL3.

- **0b0**: Accesses from EL2, EL1, and EL0 to Activity Monitor registers are not trapped.
- **0b1**: Accesses from EL2, EL1, and EL0 to Activity Monitor registers are trapped to EL3.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
Bits [29:21]
Reserved, RES0.

TTA, bit [20]
Traps System register accesses to the trace registers, from all Exception levels, both Security states, and both Execution states, to EL3.

0b0 This control does not cause any instructions to be trapped.
0b1 Any System register access to the trace registers is trapped to EL3, subject to the exception prioritization rules, unless it is trapped by CPACR.TRCDIS, CPACR_EL1.TTA or CPTR_EL2.TTA.

If System register access to trace functionality is not supported, this bit is RES0.
This field resets to an architecturally UNKNOWN value.

Bits [19:11]
Reserved, RES0.

TFP, bit [10]
Traps all accesses to SVE, Advanced SIMD and floating-point functionality, from all Exception levels, both Security states, and both Execution states, to EL3. Defined values are:

0b0 This control does not cause any instructions to be trapped.
0b1 Any attempt at any Exception level to execute an instruction that uses the registers associated with SVE, Advanced SIMD and floating-point is trapped to EL3, subject to the exception prioritization rules, unless it is trapped by CPTR_EL3.EZ.

This field resets to an architecturally UNKNOWN value.

Bit [9]
Reserved, RES0.

EZ, bit [8]
When SVE is implemented:
Traps all accesses to SVE functionality and registers from all Exception levels, and both Security states, to EL3.

0b0 This control causes these instructions executed at any Exception level to be trapped, subject to the exception prioritization rules.
0b1 This control does not cause any instruction to be trapped.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [7:0]
Reserved, RES0.

Accessing the CPTR_EL3
This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

</tbody>
</table>
D12.2.32 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

**Purpose**

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

**Configurations**

AArch64 System register CSSELR_EL1[31:0] is architecturally mapped to AArch32 System register CSSELR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CSSELR_EL1 is a 64-bit register.

**Field descriptions**

The CSSELR_EL1 bit assignments are:

**Bits [63:4]**

Reserved, RES0.

**Level, bits [3:1]**

Cache level of required cache.

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>Level 1 cache.</td>
<td></td>
<td></td>
<td></td>

</tr>
<tr>
<td>0b110</td>
<td>Level 7 cache.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

All other values are reserved.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**InD, bit [0]**

Instruction not Data bit.

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>Data or unified cache.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1b</td>
<td>Instruction cache.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

This field resets to an architecturally UNKNOWN value.
**Accessing the CSSELR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSSELR_EL1</td>
<td>11</td>
<td>000</td>
<td>010</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TID2 == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TID2 == 1, then accesses at EL1 are trapped to EL2.
D12.2.33 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

Configurations

AArch64 System register CTR_EL0[31:0] is architecturally mapped to AArch32 System register CTR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CTR_EL0 is a 64-bit register.

Field descriptions

The CTR_EL0 bit assignments are:

- **Bits [63:32]**: Reserved, RES0.
- **Bit [31]**: Reserved, RES1.
- **Bit [30]**: Reserved, RES0.
- **DIC, bit [29]**: Instruction cache invalidation requirements for instruction to data coherence. The meaning of this bit is:
  - **0b0**: Instruction cache invalidation to the Point of Unification is required for instruction to data coherence.
  - **0b1**: Instruction cache cleaning to the Point of Unification is not required for instruction to data coherence.
- **IDC, bit [28]**: Data cache clean requirements for instruction to data coherence. The meaning of this bit is:
  - **0b0**: Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR_EL1.LoC == 0b000 or (CLIDR_EL1.LoUIS == 0b000 & CLIDR_EL1.LoUU == 0b000).
  - **0b1**: Data cache clean to the Point of Unification is not required for instruction to data coherence.
CWG, bits [27:24]

Cache writeback granule. Log$_2$ of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of $0b0000$ indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than $0b1001$ are reserved.

ARM recommends that an implementation that does not support cache write-back implements this field as $0b0001$. This applies, for example, to an implementation that supports only write-through caches.

ERG, bits [23:20]

Exclusives reservation granule. Log$_2$ of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of $0b0000$ indicates that this register does not provide Exclusives reservation granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than $0b1001$ are reserved.

DminLine, bits [19:16]

Log$_2$ of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- $0b00$: VMID aware Physical Index, Physical tag (VPIPT)
- $0b01$: ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- $0b10$: Virtual Index, Physical Tag (VIPT)
- $0b11$: Physical Index, Physical Tag (PIPT)

The value $0b01$ is reserved in ARMv8.

The value $0b00$ is permitted only in an implementation that includes ARMv8.2-VPIPT, otherwise the value is reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log$_2$ of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing the CTR_EL0

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTR_EL0</td>
<td>11</td>
<td>0000</td>
<td>011</td>
<td>001</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If SCTLR_EL1.UCT == 0 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then read accesses at EL0 are trapped to EL1.
- If SCTLR_EL1.UCT == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TID2 == 1, then read accesses at EL0 or EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TID2 == 1, then read accesses at EL0 or EL1 are trapped to EL2.
D12.2.34 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 DACR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**

AArch64 System register DACR32_EL2[31:0] is architecturally mapped to AArch32 System register DACR[31:0].

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DACR32_EL2 is a 64-bit register.

**Field descriptions**

The DACR32_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>63 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>D15 D14 D13 D12 D11 D10 D9 D8 D7 D6 D5 D4 D3 D2 D1 D0</td>
</tr>
</tbody>
</table>

- **Reserved, RES0.**
- **D<n>, bits [2n+1:2n], for n = 0 to 15**
  - Domain n access permission, where n = 0 to 15. Permitted values are:
    - 0b00: No access. Any access to the domain generates a Domain fault.
    - 0b01: Client. Accesses are checked against the permission bits in the translation tables.
    - 0b11: Manager. Accesses are not checked against the permission bits in the translation tables.
  - The value 0b10 is reserved.
  - This field resets to an architecturally UNKNOWN value.

**Accessing the DACR32_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DACR32_EL2</td>
<td>11</td>
<td>0011</td>
<td>100</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 1 & HCR_EL2.TGE == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.35 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

**Purpose**

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Address) System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DCZID_EL0 is a 64-bit register.

**Field descriptions**

The DCZID_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:5]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>DZP, bit [4]</td>
<td>Data Zero Prohibited. This field indicates whether use of DC ZVA instructions is permitted or prohibited.</td>
</tr>
<tr>
<td>BS, bits [3:0]</td>
<td>Log$_2$ of the block size in words. The maximum size supported is 2KB (value == 9).</td>
</tr>
</tbody>
</table>

**Accessing the DCZID_EL0**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCZID_EL0</td>
<td>11</td>
<td>0000</td>
<td>011</td>
<td>111</td>
<td>0000</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.36 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

**Purpose**
Holds syndrome information for an exception taken to EL1.

**Configurations**
AArch64 System register ESR_EL1[31:0] is architecturally mapped to AArch32 System register DFSR[31:0].
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
ESR_EL1 is a 64-bit register.

**Field descriptions**
The ESR_EL1 bit assignments are:

![ESR_EL1 Bit Assignment Diagram]

ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Bits [63:32]**
Reserved, RES0.

**EC, bits [31:26]**
Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:
- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 0b000000**
Unknown reason.
See *ISS encoding for exceptions with an unknown reason* on page D12-2774.

**EC == 0b000001**
Trapped WFI or WFE instruction execution.
Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.
See *ISS encoding for an exception from a WFI or WFE instruction* on page D12-2776.

**EC == 0b000011**
Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.
See *ISS encoding for an exception from an MCR or MRC access* on page D12-2777.
EC == 0b000100
Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.
See ISS encoding for an exception from an MCRR or MRRC access on page D12-2779.

EC == 0b000101
Trapped MCR or MRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCR or MRC access on page D12-2777.

EC == 0b000110
Trapped LDC or STC access.
The only architected uses of these instruction are:
- An STC to write data to memory from DBGDTTRXint.
- An LDC to read data from memory to DBGDTTRXint.
See ISS encoding for an exception from an LDC or STC instruction on page D12-2781.

EC == 0b000111
Access to SVE, Advanced SIMD, or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.
Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2177.
See ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP on page D12-2783.

EC == 0b001100
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access on page D12-2779.

EC == 0b001110
Illegal Execution state.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2785.

EC == 0b010001
SVC instruction execution in AArch32 state.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.
See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2785.

EC == 0b010101
SVC instruction execution in AArch64 state.
See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2785.

EC == 0b011000
Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111, or an exception generated on a read of an ID register.
This includes all instructions that cause exceptions that are part of the encoding space defined in System instruction class encoding overview on page C5-339, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.
See ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register on page D12-2788.
EC == 0b011001
Access to SVE functionality trapped as a result of CPACR_EL1.ZEN,
CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC
0b000000.
This EC is defined only if SVE is implemented.
See ISS encoding for an exception from an access to SVE functionality, resulting from
CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ on
page D12-2785.

EC == 0b100000
Instruction Abort from a lower Exception level, that might be using AArch32 or
AArch64.
Used for MMU faults generated by instruction accesses and synchronous External
aborts, including synchronous parity or ECC errors. Not used for debug related
exceptions.
See ISS encoding for an exception from an Instruction Abort on page D12-2790.

EC == 0b100001
Instruction Abort taken without a change in Exception level.
Used for MMU faults generated by instruction accesses and synchronous External
aborts, including synchronous parity or ECC errors. Not used for debug related
exceptions.
See ISS encoding for an exception from an Instruction Abort on page D12-2790.

EC == 0b100010
PC alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP
alignment fault on page D12-2785.

EC == 0b100100
Data Abort from a lower Exception level, that might be using AArch32 or AArch64.
Used for MMU faults generated by data accesses, alignment faults other than those
causled by Stack Pointer misalignment, and synchronous External aborts, including
synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data Abort on page D12-2792.

EC == 0b100101
Data Abort taken without a change in Exception level.
Used for MMU faults generated by data accesses, alignment faults other than those
causled by Stack Pointer misalignment, and synchronous External aborts, including
synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data Abort on page D12-2792.

EC == 0b100110
SP alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP
alignment fault on page D12-2785.

EC == 0b101000
Trapped floating-point exception taken from AArch32 state.
This EC value is valid if the implementation supports trapping of floating-point
exceptions, otherwise it is reserved. Whether a floating-point implementation supports
trapping of floating-point exceptions is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped floating-point exception on
page D12-2796.

EC == 0b101100
Trapped floating-point exception taken from AArch64 state.
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.

See ISS encoding for an exception from a trapped floating-point exception on page D12-2796.

EC == 0b101111
SError interrupt.
See ISS encoding for an SError interrupt on page D12-2798.

EC == 0b110000
Breakpoint exception from a lower Exception level, that might be using AArch32 or AArch64.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D12-2800.

EC == 0b110001
Breakpoint exception taken without a change in Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D12-2800.

EC == 0b110010
Software Step exception from a lower Exception level, that might be using AArch32 or AArch64.
See ISS encoding for an exception from a Software Step exception on page D12-2800.

EC == 0b110011
Software Step exception taken without a change in Exception level.
See ISS encoding for an exception from a Software Step exception on page D12-2800.

EC == 0b111000
Watchpoint exception from a lower Exception level, that might be using AArch32 or AArch64.
See ISS encoding for an exception from a Watchpoint exception on page D12-2801.

EC == 0b111010
Watchpoint exception taken without a change in Exception level.
See ISS encoding for an exception from a Watchpoint exception on page D12-2801.

EC == 0b111000
BKPT instruction execution in AArch32 state.
See ISS encoding for an exception from execution of a Breakpoint instruction on page D12-2802.

EC == 0b111100
BRK instruction execution in AArch64 state.
This is reported in ESR_EL3 only if a BRK instruction is executed.
See ISS encoding for an exception from execution of a Breakpoint instruction on page D12-2802.

All other EC values are reserved by ARM, and:
• Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
• Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7216.

This field resets to an architecturally UNKNOWN value.
IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

0b0  16-bit instruction trapped.
0b1  • An SError interrupt.
     • An Instruction Abort exception.
     • A PC alignment fault exception.
     • An SP alignment fault exception.
     • A Data Abort exception for which the value of the ISV bit is 0.
     • An Illegal Execution state exception.
     • Any debug exception except for Breakpoint instruction exceptions. For
       Breakpoint instruction exceptions, this bit has its standard meaning:
       — 0b0: 16-bit T32 BKPT instruction.
       — 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
     • An exception reported using EC value 0b000000.

This field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each
defined Exception class. However, in practice, some ISS encodings are used for more than one
Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number,
the value returned in that field is the AArch64 view of the register number. For an exception taken
from AArch32 state, Mapping of the general-purpose registers between the Execution states on
page D1-2264 defines this view of the specified AArch32 register. If the AArch32 register
descriptor is 0b1111, then:

• If the instruction that generated the exception was not UNPREDICTABLE, the field takes the
  value 0b11111.
• If the instruction that generated the exception was UNPREDICTABLE, the field takes an
  UNKNOWN value that must be either:
    — The AArch64 view of the register number of a register that might have been used at
      the Exception level from which the exception was taken.
    — The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not
valid, RES0.

The following subsections describe each ISS format.

**ISS encoding for exceptions with an unknown reason**

```
  24  0
   RES0
```

Bits [24:0]

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.
This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions not implemented in the implementation.

- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.

- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.

- In AArch32 state, attempted execution of a short vector floating-point instruction.

- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.

- An exception generated because of the value of one of the SCTLR_EL1.ITD, SED, CP15BEN control bits.

- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.

- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.

- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.

- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.

- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.

- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0b000111.

- When SVE is not implemented, attempted execution of:
  - An SVE instruction.
  - An MSR or MRS instruction to access ZCR_EL1, ZCR_EL2, or ZCR_EL3.
ISS encoding for an exception from a WFI or WFE instruction

<table>
<thead>
<tr>
<th>24</th>
<th>23</th>

<th>19</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CV</td>
<td>COND</td>
<td>RES0</td>
<td>TI</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

CV, bit [24]
Condition code valid. Possible values of this bit are:
- 0b0: The COND field is not valid.
- 0b1: The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

Bits [19:1]
Reserved, RES0.

TI, bit [0]
Trapped instruction. Possible values of this bit are:
- 0b0: WFI trapped.
WFE trapped.
This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating this exception:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2211.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2229.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2244.

</table>

**CV, bit [24]**
Condition code valid. Possible values of this bit are:
- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.
For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \(0b1110\), or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Opc2, bits [19:17]**

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value \(0b000\).

This field resets to an architecturally UNKNOWN value.

**Opc1, bits [16:14]**

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value \(0b111\).

This field resets to an architecturally UNKNOWN value.

**CRn, bits [13:10]**

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.

This field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value \(0b0000\).

This field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

0b0  Write to System register space. MCR instruction.

0b1  Read from System register space. MRC or VMRS instruction.

This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000011\):

•  **Traps to EL1 of EL0 accesses to the Generic Timer registers** on page D1-2215.

•  **Traps to EL1 of EL0 accesses to Performance Monitors registers** on page D1-2216.

•  **Traps to EL1 of EL0 accesses to Activity Monitors registers** on page D1-2217.

•  **Traps to EL2 of EL1 accesses to virtual memory control registers** on page D1-2221.

•  **Traps to EL2 of EL1 execution of TLB maintenance instructions** on page D1-2222.

•  **Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions** on page D1-2223.

•  **Traps to EL2 of EL1 accesses to the Auxiliary Control Register** on page D1-2224.

•  **Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations** on page D1-2225.
* Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226.
* Trapping to EL2 of EL1 accesses to the CPACR_EL1 or CPACR on page D1-2231.
* General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-2232.
* Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers on page D1-2236.
* Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2237.
* Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers on page D1-2230.
* Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.
* Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-2246.
* Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
* Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

* Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-2213.
* Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
* Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226, for trapped accesses to the JIDR.
* Traps to EL2 of System register accesses to the trace registers on page D1-2231.
* Trapping System register accesses to Debug ROM registers to EL2 on page D1-2234.
* Trapping System register accesses to powerdown debug registers to EL2 on page D1-2234.
* Trapping general System register accesses to debug registers to EL2 on page D1-2235.
* Traps to EL3 of System register accesses to the trace registers on page D1-2247.
* Trapping System register accesses to powerdown debug registers to EL3 on page D1-2249.
* Trapping general System register accesses to debug registers to EL3 on page D1-2249.

*Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226* describes configuration settings for generating exceptions that are reported using EC value 0b001000.

CV, bit [24]

Condition code valid. Possible values of this bit are:

0b0 The COND field is not valid.
0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Bit [15]**

Reserved, RES0.

**Rt2, bits [14:10]**

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states on page D1-2264.*

This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the first general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states on page D1-2264.*

This field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

This field resets to an architecturally UNKNOWN value.
Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0b0  Write to System register space. MCRR instruction.
- 0b1  Read from System register space. MRRC instruction.

This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-2215.
- Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-2216.
- Traps to EL1 of EL0 accesses to Activity Monitors registers on page D1-2217.
- Traps to EL2 of EL1 accesses to virtual memory control registers on page D1-2221.
- General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-2232.
- Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers on page D1-2236.
- Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2237.
- Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers on page D1-2230.
- Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
- Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-2213.
- Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
- Traps to EL2 of System register accesses to the trace registers on page D1-2231.
- Trapping System register accesses to Debug ROM registers to EL2 on page D1-2234.
- Traps to EL3 of System register accesses to the trace registers on page D1-2247.
- Trapping System register accesses to powerdown debug registers to EL3 on page D1-2249.
- Trapping general System register accesses to debug registers to EL3 on page D1-2249.

**ISS encoding for an exception from an LDC or STC instruction**

```
   24 23  20 19  12 11  10  9  5  4  3  1  0
   +---+---+---+---+---+---+---+
   | COND | imm8 | Rn | AM |
   +---+---+---+---+---+---+---+
```

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0b0  The COND field is not valid.
COND, bits [23:20]
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]
The immediate value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

Bits [11:10]
Reserved, RES0.

Rn, bits [9:5]
The Rn value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

Offset, bit [4]
Indicates whether the offset is added or subtracted:
- 0b0 Subtract offset.
0b1
Add offset.
This bit corresponds to the U bit in the instruction encoding.
This field resets to an architecturally UNKNOWN value.

AM, bits [3:1]
Addressing mode. The permitted values of this field are:
0b000 Immediate unindexed.
0b001 Immediate post-indexed.
0b010 Immediate offset.
0b011 Immediate pre-indexed.
0b100 For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110 For a trapped STC instruction, this encoding is reserved.
The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

Bit [2] in this subfield indicates the instruction form, immediate or literal.
Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.
This field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0b0 Write to memory. STC instruction.
0b1 Read from memory. LDC instruction.
This field resets to an architecturally UNKNOWN value.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000110:

• Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
• Trapping general System register accesses to debug registers to EL2 on page D1-2235.
• Trapping general System register accesses to debug registers to EL3 on page D1-2249.

ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP

The accesses covered by this trap include:

• Execution of SVE or Advanced SIMD and floating-point instructions.
• Accesses to the Advanced SIMD and floating-point System registers.
For an implementation that does not include either SVE or support for floating-point and Advanced SIMD, the exception is reported using the EC value 0b000000.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [19:0]**

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- *Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality* on page D1-2214.
- *General trapping to EL2 of accesses to the SIMD and floating-point registers* on page D1-2231.
- *Traps to EL3 of all accesses to the SIMD and floating-point registers* on page D1-2248
**ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ**

![ISS encoding](image)

**Bits [24:0]**

*When SVE is implemented:*

Reserved, RES0.

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE system registers, ZCR_ELx and ID_AA64ZFR0_EL1.

For an implementation that does not include SVE, the exception is reported using the EC value `0b000000`.

**ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

![ISS encoding](image)

**Bits [24:0]**

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions see *The Illegal Execution state exception* on page D1-2182 and *PC alignment checking* on page D1-2164.

*SP alignment checking* on page D1-2164 describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from HVC or SVC instruction execution**

![ISS encoding](image)

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.

- If the instruction is conditional, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see SVC and HVC.

For A64 instructions, see SVC and HVC.

**ISS encoding for an exception from SMC instruction execution in AArch32 state**

```
<table>
<thead>
<tr>
<th>24 23</th>
<th>20 19 18</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CV</td>
<td>CCKNOWNPASS</td>
<td>RES0</td>
</tr>
<tr>
<td>COND</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0b0: The COND field is not valid.
- 0b1: The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to $0b1110$, or to the value of any condition that applied to the instruction.

This field is only valid if CCKOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

**CCKOWNPASS, bit [19]**

Indicates whether the instruction might have failed its condition code check.

- $0b0$: The instruction was unconditional, or was conditional and passed its condition code check.
- $0b1$: The instruction was conditional, and might have failed its condition code check.

**Note**

In an implementation in which an SMC instruction that fails it code check is not trapped, this field can always return the value 0.

This field resets to an architecturally UNKNOWN value.

**Bits [18:0]**

Reserved, RES0.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.

**ISS encoding for an exception from SMC instruction execution in AArch64 state**

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>24:15</td>
<td>imm16, bits [15:0]</td>
</tr>
<tr>
<td>16</td>
<td>RES0</td>
</tr>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
</tbody>
</table>
```

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the issued SMC instruction.

This field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.
ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register

— Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
— Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.

**ISS encoding for a IMPLEMENTATION DEFINED exception to EL3**

<table>
<thead>
<tr>
<th>24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from an Instruction Abort**

<table>
<thead>
<tr>
<th>24</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SET</td>
<td>IFSC</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:13]**

Reserved, RES0.

**SET, bits [12:11]**

Synchronous Error Type. When the RAS Extension is implemented and IFSC is \(0b010000\), describes the state of the PE after taking the Instruction Abort exception. The possible values of this field are:

- \(0b0\) Recoverable error (UER).
- \(0b10\) Uncontainable error (UC).
- \(0b11\) Restartable error (UEO) or Corrected error (CE).

All other values are reserved.

--- **Note** ---

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

---

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the IFSC field is not \(0b010000\).

This field resets to an architecturally UNKNOWN value.

**FnV, bit [10]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- \(0b0\) FAR is valid.
- \(0b1\) FAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is \(0b010000\). It is RES0 for all other aborts.

This field resets to an architecturally UNKNOWN value.

**EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field resets to an architecturally UNKNOWN value.

**Bit [8]**

Reserved, RES0.
S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- \(0\) Fault not on a stage 2 translation for a stage 1 translation table walk.
- \(1\) Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is \(0\).
This field resets to an architecturally \textit{UNKNOWN} value.

Bit [6]

Reserved, \(0\).

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

- \(000000\) Address size fault, level 0 of translation or translation table base register
- \(000001\) Address size fault, level 1
- \(000010\) Address size fault, level 2
- \(000011\) Address size fault, level 3
- \(000100\) Translation fault, level 0
- \(000101\) Translation fault, level 1
- \(000110\) Translation fault, level 2
- \(000111\) Translation fault, level 3
- \(001001\) Access flag fault, level 1
- \(001010\) Access flag fault, level 2
- \(001011\) Access flag fault, level 3
- \(001101\) Permission fault, level 1
- \(001110\) Permission fault, level 2
- \(001111\) Permission fault, level 3
- \(010000\) Synchronous External abort, not on translation table walk
- \(010100\) Synchronous External abort, on translation table walk, level 0
- \(010101\) Synchronous External abort, on translation table walk, level 1
- \(010110\) Synchronous External abort, on translation table walk, level 2
- \(010111\) Synchronous External abort, on translation table walk, level 3
- \(011000\) Synchronous parity or ECC error on memory access, not on translation table walk
- \(011100\) Synchronous parity or ECC error on memory access on translation table walk, level 0
- \(011101\) Synchronous parity or ECC error on memory access on translation table walk, level 1
- \(011110\) Synchronous parity or ECC error on memory access on translation table walk, level 2
- \(011111\) Synchronous parity or ECC error on memory access on translation table walk, level 3
- \(011000\) TLB conflict abort
- \(011001\) Unsupported atomic hardware update fault, if the implementation includes \textit{ARMv8.1-TTHM}. Otherwise reserved.

All other values are reserved.
When the RAS Extension is implemented, \(0011100, 0011101, 0011110, 0011111\), and \(0011111\), are reserved.

\textbf{Note}

\textit{ARMv8.2} requires the implementation of the RAS Extension.
For more information about the lookup level associated with a fault, see *The level associated with MMU faults* on page D5-2505.

---

**Note**

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

---

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally **UNKNOWN** value.

**ISS encoding for an exception from a Data Abort**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No valid instruction syndrome. ISS[23:0] are RES0.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0b1</td>
<td>ISS[23:14] hold a valid instruction syndrome.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback.
- AArch32 instructions where the instruction:
  - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDB, LDRBT, STR, ST, STRT, STRH, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using R15 as a source or destination register.

For these cases, ISV is **UNKNOWN** if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

When the RAS Extension is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When the RAS Extension is not implemented, the value of ISV on a synchronous External abort on a stage 2 translation table walk is **IMPLEMENTATION DEFINED**.

This field resets to an architecturally **UNKNOWN** value.

**SAS, bits [23:22]**

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

0b00   Byte
SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

\[ 0b0 \text{ Sign-extension not required.} \]
\[ 0b1 \text{ Data item must be sign-extended.} \]

For all other operations this bit is 0.

This field is unknown when the value of ISV is unknown.
This field is RES0 when the value of ISV is 0.
This field resets to an architecturally unknown value.

SRT, bits [20:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction. If the exception was taken from an Exception level that is using AArch32 then this is the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.

This field is unknown when the value of ISV is unknown.
This field is RES0 when the value of ISV is 0.
This field resets to an architecturally unknown value.

SF, bit [15]

Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

\[ 0b0 \text{ Instruction loads/stores a 32-bit wide register.} \]
\[ 0b1 \text{ Instruction loads/stores a 64-bit wide register.} \]

Note: This field specifies the register width identified by the instruction, not the Execution state.

This field is unknown when the value of ISV is unknown.
This field is RES0 when the value of ISV is 0.
This field resets to an architecturally unknown value.

AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

\[ 0b0 \text{ Instruction did not have acquire/release semantics.} \]
\[ 0b1 \text{ Instruction did have acquire/release semantics.} \]

This field is unknown when the value of ISV is unknown.
This field is RES0 when the value of ISV is 0.
This field resets to an architecturally unknown value.
VNCR, bit [13]
Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

0b0 The fault was not generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.
0b1 The fault was generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.
This field resets to an architecturally UNKNOWN value.

SET, bits [12:11]
Synchronous Error Type. When the RAS Extension is implemented and DFSC is 0b010000, describes the state of the PE after taking the Data Abort exception. The possible values of this field are:

0b00 Recoverable error (UER).
0b10 Uncontainable error (UC).
0b11 Restartable error (UEO) or Corrected error (CE).

All other values are reserved.

Note
Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:
• The RAS Extension is not implemented.
• The value returned in the DFSC field is not 0b010000.
This field resets to an architecturally UNKNOWN value.

FnV, bit [10]
FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.
0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.
This field resets to an architecturally UNKNOWN value.

EA, bit [9]
External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.
For any abort other than an External abort this bit returns a value of 0.
This field resets to an architecturally UNKNOWN value.

CM, bit [8]
Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0 The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZV A instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

This field resets to an architecturally UNKNOWN value.
S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0b0: Fault not on a stage 2 translation for a stage 1 translation table walk.
- 0b1: Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

This field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

- 0b0: Abort caused by an instruction reading from a memory location.
- 0b1: Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:
- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

This field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

- 0b000000: Address size fault, level 0 of translation or translation table base register.
- 0b000001: Address size fault, level 1.
- 0b000010: Address size fault, level 2.
- 0b000011: Address size fault, level 3.
- 0b000100: Translation fault, level 0.
- 0b000101: Translation fault, level 1.
- 0b000110: Translation fault, level 2.
- 0b000111: Translation fault, level 3.
- 0b001001: Access flag fault, level 1.
- 0b001010: Access flag fault, level 2.
- 0b001011: Access flag fault, level 3.
- 0b001101: Permission fault, level 1.
- 0b001110: Permission fault, level 2.
- 0b001111: Permission fault, level 3.
- 0b010000: Synchronous External abort, not on translation table walk.
- 0b010001: Synchronous Tag Check fail
- 0b010100: Synchronous External abort, on translation table walk, level 0.
- 0b010101: Synchronous External abort, on translation table walk, level 1.
- 0b010110: Synchronous External abort, on translation table walk, level 2.
0b010111  Synchronous External abort, on translation table walk, level 3.
0b011000  Synchronous parity or ECC error on memory access, not on translation table walk.
0b011100  Synchronous parity or ECC error on memory access on translation table walk, level 0.
0b011101  Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011110  Synchronous parity or ECC error on memory access on translation table walk, level 2.
0b011111  Synchronous parity or ECC error on memory access on translation table walk, level 3.
0b100001  Alignment fault.
0b110000  TLB conflict abort.
0b110001  Unsupported atomic hardware update fault, if the implementation includes Armv8.1-TTHM. Otherwise reserved.
0b110100  IMPLEMENTATION DEFINED fault (Lockdown).
0b110101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).
0b111100  IMPLEMENTATION DEFINED fault (Lockdown).
0b110100  IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).
0b111101  Section Domain Fault, used only for faults reported in the PAR_EL1.
0b111110  Page Domain Fault, used only for faults reported in the PAR_EL1.
All other values are reserved.
When the RAS Extension is implemented, 0b011000, 0b011100, 0b011101, 0b011110, and 0b011111, are reserved.
For more information about the lookup level associated with a fault, see The level associated with MMU faults on page D5-2505.

--- Note ---

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

---

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a trapped floating-point exception**

![ISS Encoding Diagram]

**Bit [24]**

Reserved, RES0.

**TFV, bit [23]**

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions. The possible values of this bit are:

- **0b0**: The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information see Floating-point exceptions and exception traps on page D1-2196.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating point exception from a vector instruction.

--- Note ---

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from a vector instruction and return valid information in the \{IDF, IXF, UFF, OFF, DZF, IOF\} fields.

This field resets to an architecturally UNKNOWN value.

**Bits [22:11]**

Reserved, RES0.

**VECITR, bits [10:8]**

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**IDF, bit [7]**

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Input denormal floating-point exception has not occurred.
- 0b1: Input denormal floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [6:5]**

Reserved, RES0.

**IXF, bit [4]**

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Inexact floating-point exception has not occurred.
- 0b1: Inexact floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**UFF, bit [3]**

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Underflow floating-point exception has not occurred.
- 0b1: Underflow floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**OFF, bit [2]**

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Overflow floating-point exception has not occurred.
0b1  Overflow floating-point exception occurred during execution of the reported instruction. 
This field resets to an architecturally UNKNOWN value.

**DZF, bit [1]**

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0  Divide by Zero floating-point exception has not occurred.
0b1  Divide by Zero floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**IOF, bit [0]**

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0  Invalid Operation floating-point exception has not occurred.
0b1  Invalid Operation floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

**ISS encoding for an SError interrupt**

![ISS encoding diagram]

**IDS, bit [24]**

IMPLEMENTATION DEFINED syndrome. Possible values of this bit are:

0b0  Bits[23:0] of the ISS field holds the fields described in this encoding.

--- **Note** ---

If the RAS Extension is not implemented, this means that bits[23:0] of the ISS field are RES0.

--- **Note** ---

0b1  Bits[23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

--- **Note** ---

This field was previously called ISV.

This field resets to an architecturally UNKNOWN value.
Bits [23:14]
Reserved, RES0.

IESB, bit [13]
Implicit error synchronization event.

0b0 The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1 The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is RES0 if the value returned in the DFSC field is not 0b010001.

Note
ARMv8.2 requires the implementation of the RAS Extension and ARMv8.2-IESB.

This field resets to an architecturally UNKNOWN value.

AET, bits [12:10]
Asynchronous Error Type.
When the RAS Extension is implemented and DFSC is 0b010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

0b000 Uncontainable error (UC).
0b001 Unrecoverable error (UEU).
0b010 Restartable error (UEO).
0b011 Recoverable error (UER).
0b100 Corrected error (CE).
All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

Note
Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010001.

Note
ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

EA, bit [9]
External abort type. When the RAS Extension is implemented, this bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010001.
**Note**

ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

**Bits [8:6]**

Reserved, RES0.

**DFSC, bits [5:0]**

Data Fault Status Code. When the RAS Extension is implemented, possible values of this field are:
- 0b000000 Uncategorized.
- 0b010001 Asynchronous SError interrupt.
- All other values are reserved.

If the RAS Extension is not implemented, this field is RES0.

**Note**

ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a Breakpoint or Vector Catch debug exception**

```
<table>
<thead>
<tr>
<th>24</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>IFSC</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions:

- For exceptions from AArch64, see *Breakpoint exceptions* on page D2-2296.
- For exceptions from AArch32, see *Breakpoint exceptions* on page G2-5366 and *Vector Catch exceptions* on page G2-5405.

**ISS encoding for an exception from a Software Step exception**

```
<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>
```

<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISV</td>
<td></td>
<td>IFSC</td>
<td>EX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

- 0b0 EX bit is RES0.
- 0b1 EX bit is valid.
See the EX bit description for more information.
This field resets to an architecturally UNKNOWN value.

Bits [23:7]
Reserved, RES0.

EX, bit [6]
Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.
0b0 An instruction other than a Load-Exclusive instruction was stepped.
0b1 A Load-Exclusive instruction was stepped.
If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.
This field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]
Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.
This field resets to an architecturally UNKNOWN value.
For more information about generating these exceptions, see Software Step exceptions on page D2-2329.

**ISS encoding for an exception from a Watchpoint exception**

<table>
<thead>
<tr>
<th></th>
<th>24</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>RES0</td>
<td>DFSC</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>VNCR</td>
<td>RES0</td>
<td>RES0</td>
<td>CM</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [24:14]
Reserved, RES0.

VNCR, bit [13]
Indicates that the watchpoint came from use of VNR_EL2 register by EL1 code.
0b0 The watchpoint was not generated by the use of VNR_EL2 by EL1 code.
0b1 The watchpoint was generated by the use of VNR_EL2 by EL1 code.
This field is 0 in ESR_EL1.
This field resets to an architecturally UNKNOWN value.

Bits [12:9]
Reserved, RES0.

CM, bit [8]
Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:
0b0 The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1 The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.
This field resets to an architecturally UNKNOWN value.

**Bit [7]**

Reserved, RES0.

**WnR, bit [6]**

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

- **0b0**: Watchpoint exception caused by an instruction reading from a memory location.
- **0b1**: Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance and address translation instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

This field resets to an architecturally UNKNOWN value.

**DFSC, bits [5:0]**

Data Fault Status Code. This field is set to **0b100010**, to indicate a Debug exception.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-2314.

**ISS encoding for an exception from execution of a Breakpoint instruction**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Comment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:16]**

Reserved, RES0.

**Comment, bits [15:0]**

Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT instructions, the comment field is described as the immediate field.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Breakpoint Instruction exceptions* on page D2-2294.

**ISS encoding for an exception from ERET, ERETA or ERETAB instruction**

<table>
<thead>
<tr>
<th>24</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| ERETA | ERET |
This EC value only applies when HCR_EL2.NV is 1.

**Bits [24:2]**

Reserved, RES0.

**ERET, bit [1]**

Indicates whether an ERET or ERETA* instruction was trapped to EL2. Possible values are:

- **0b0**: ERET instruction trapped to EL2.
- **0b1**: ERETA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

This field resets to an architecturally **UNKNOWN** value.

**ERETA, bit [0]**

Indicates whether an ERETAA or ERETAB instruction was trapped to EL2. Possible values are:

- **0b0**: ERETAA instruction trapped to EL2.
- **0b1**: ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

This field resets to an architecturally **UNKNOWN** value.

For more information about generating these exceptions, see *Traps to EL2 for Nested virtualization* on page D1-2240.

**ISS encoding for an exception from Branch Target Identification instruction**

```
  24 2 1 0
  RES0
  BTYPE
```

**Bits [24:2]**

Reserved, RES0.

**BTYPE, bits [1:0]**

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see *Chapter B1 The AArch64 Application Level Programmers’ Model*.

**ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0**

```
  24 0
  RES0
```

**Bits [24:0]**

Reserved, RES0.

For more information about generating these exceptions, see:

- *Trap to EL2 of EL0 accesses to Pointer authentication instructions* on page D1-2239.
• *Trap to EL3 accesses to Pointer authentication instructions* on page D1-2252.

**Accessing the ESR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR_EL1</td>
<td>11</td>
<td>0101</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
<tr>
<td>ESR_EL12</td>
<td>11</td>
<td>0101</td>
<td>101</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 - RW EL1 n/a EL2 RW</td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>HCR_EL2.NV == 1 &amp; &amp; HCR_EL2.NV1 == 1 &amp; &amp; HCR_EL2.NV2 == 1 &amp; &amp; HCR_EL2.TGE == 0 &amp; &amp; HCR_EL2.E2H == 0 &amp; &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic ESR_EL1 or ESR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If IsUsingAccessor(ESR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(ESR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(ESR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(ESR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(ESR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(ESR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(ESR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(ESR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(ESR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.
D12.2.37 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL2.

**Configurations**

AArch64 System register ESR_EL2[31:0] is architecturally mapped to AArch32 System register HSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ESR_EL2 is a 64-bit register.

**Field descriptions**

The ESR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32 31</th>
<th>26 25 24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EC</td>
<td>IL</td>
<td>ISS</td>
</tr>
</tbody>
</table>

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Bits [63:32]**

Reserved, RES0.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about. For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 0b000000**

Unknown reason.

See [ISS encoding for exceptions with an unknown reason on page D12-2812](#).

**EC == 0b000001**

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WFI or WFE instruction on page D12-2813](#).

**EC == 0b000011**

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.
See ISS encoding for an exception from an MCR or MRC access on page D12-2815.

### EC == 0b0000100

Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See ISS encoding for an exception from an MCRR or MRRC access on page D12-2817.

### EC == 0b0000101

Trapped MCR or MRC access with (coproc==0b1110).

See ISS encoding for an exception from an MCR or MRC access on page D12-2815.

### EC == 0b0000110

Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from DBGDTRRXint.
- An LDC to read data from memory to DBGDTRTXint.

See ISS encoding for an exception from an LDC or STC instruction on page D12-2819.

### EC == 0b0001011

Access to SVE, Advanced SIMD, or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.

Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2177.

See ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP on page D12-2821.

### EC == 0b0001100

Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

See ISS encoding for an exception from an MCR or MRC access on page D12-2815.

### EC == 0b0001001 From ARMv8.3

Trapped use of a Pointer authentication instruction because HCR_EL2.API == 0 || SCR_EL3.API == 0.

See ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0 on page D12-2841.

### EC == 0b0011100

Illegal Execution state.

See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2823.

### EC == 0b0100101

SVC instruction execution in AArch32 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.

See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2823.

### EC == 0b0100010

HVC instruction execution in AArch32 state, when HVC is not disabled.

See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2823.
EC == 0b010011
SMC instruction execution in AArch32 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of
HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch32 state
on page D12-2824.

EC == 0b010101
SVC instruction execution in AArch64 state.
See ISS encoding for an exception from HVC or SVC instruction execution
on page D12-2823.

EC == 0b010110
HVC instruction execution in AArch64 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution
on page D12-2823.

EC == 0b010111
SMC instruction execution in AArch64 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of
HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch64 state
on page D12-2825.

EC == 0b011000
Trapped MSR, MRS or System instruction execution in AArch64 state, that is not
reported using EC 0b000000, 0b000001 or 0b000111, or an exception generated on a read
of an ID register.
This includes all instructions that cause exceptions that are part of the encoding space
defined in System instruction class encoding overview on page C5-339, except for those
exceptions reported using EC values 0b000000, 0b000001, or 0b000111.
See ISS encoding for an exception from MSR, MRS, or System instruction execution in
AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register
on page D12-2826.

EC == 0b011001
Access to SVE functionality trapped as a result of CPACR_EL1.ZEN,
CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC
0b000000.
This EC is defined only if SVE is implemented.
See ISS encoding for an exception from an access to SVE functionality, resulting from
CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ on
page D12-2822.

EC == 0b011010 From ARMv8.3
Trapped ERET, ERETTAA, or ERETAB instruction execution.
See ISS encoding for an exception from ERET, ERETTAA or ERETAB instruction
on page D12-2840.

EC == 0b100000
Instruction Abort from a lower Exception level, that might be using AArch32 or
AArch64.
Used for MMU faults generated by instruction accesses and synchronous External
aborts, including synchronous parity or ECC errors. Not used for debug related
exceptions.
See ISS encoding for an exception from an Instruction Abort on page D12-2828.

EC == 0b100001
Instruction Abort taken without a change in Exception level.
Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

See [ISS encoding for an exception from an Instruction Abort](#) on page D12-2828.

**EC == 0b100010**

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#) on page D12-2823.

**EC == 0b100100**

Data Abort from a lower Exception level, that might be using AArch32 or AArch64. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

See [ISS encoding for an exception from a Data Abort](#) on page D12-2830.

**EC == 0b100101**

Data Abort taken without a change in Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

See [ISS encoding for an exception from a Data Abort](#) on page D12-2830.

**EC == 0b100110**

SP alignment fault exception.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#) on page D12-2823.

**EC == 0b101000**

Trapped floating-point exception taken from AArch32 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is [IMPLEMENTATION DEFINED](#).

See [ISS encoding for an exception from a trapped floating-point exception](#) on page D12-2834.

**EC == 0b101100**

Trapped floating-point exception taken from AArch64 state.

This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is [IMPLEMENTATION DEFINED](#).

See [ISS encoding for an exception from a trapped floating-point exception](#) on page D12-2834.

**EC == 0b101111**

SError interrupt.

See [ISS encoding for an SError interrupt](#) on page D12-2836.

**EC == 0b110000**

Breakpoint exception from a lower Exception level, that might be using AArch32 or AArch64.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#) on page D12-2838.

**EC == 0b110001**

Breakpoint exception taken without a change in Exception level.

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#) on page D12-2838.
EC == 0b110010
Software Step exception from a lower Exception level, that might be using AArch32 or AArch64.
See **ISS encoding for an exception from a Software Step exception** on page D12-2838.

EC == 0b110011
Software Step exception taken without a change in Exception level.
See **ISS encoding for an exception from a Software Step exception** on page D12-2838.

EC == 0b110100
Watchpoint exception from a lower Exception level, that might be using AArch32 or AArch64.
See **ISS encoding for an exception from a Watchpoint exception** on page D12-2839.

EC == 0b110101
Watchpoint exception taken without a change in Exception level.
See **ISS encoding for an exception from a Watchpoint exception** on page D12-2839.

EC == 0b111000
BKPT instruction execution in AArch32 state.
See **ISS encoding for an exception from execution of a Breakpoint instruction** on page D12-2840.

EC == 0b111010
Vector Catch exception from AArch32 state.
The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.
See **ISS encoding for an exception from a Breakpoint or Vector Catch debug exception** on page D12-2838.

EC == 0b111100
BRK instruction execution in AArch64 state.
This is reported in ESR_EL3 only if a BRK instruction is executed.
See **ISS encoding for an exception from execution of a Breakpoint instruction** on page D12-2840.

All other EC values are reserved by ARM, and:
- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in **Reserved values in System and memory-mapped registers and translation table entries** on page K1-7216.

This field resets to an architecturally **UNKNOWN** value.

**IL, bit [25]**

Instruction Length for synchronous exceptions. Possible values of this bit are:

- **0b0** 16-bit instruction trapped.
- **0b1**
  - An SError interrupt.
  - An Instruction Abort exception.
  - A PC alignment fault exception.
  - An SP alignment fault exception.
  - A Data Abort exception for which the value of the ISV bit is 0.
  - An Illegal Execution state exception.
• Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
  — 0b0: 16-bit T32 BKPT instruction.
  — 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
• An exception reported using EC value 0b000000.

This field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]
Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number. For an exception taken from AArch32 state, Mapping of the general-purpose registers between the Execution states on page D1-2264 defines this view of the specified AArch32 register. If the AArch32 register descriptor is 0b1111, then:

• If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
• If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  — The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  — The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsections describe each ISS format.

**ISS encoding for exceptions with an unknown reason**

![ISS encoding for exceptions with an unknown reason](image)

**Bits [24:0]**
Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

• The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  — A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  — A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  — Instruction encodings for instructions not implemented in the implementation.
• In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
• In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPsel.SP is 0.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of \(0b000111\).
- When SVE is not implemented, attempted execution of:
  - An SVE instruction.
  - An MSR or MRS instruction to access ZCR_EL1, ZCR_EL2, or ZCR_EL3.

**ISS encoding for an exception from a WFI or WFE instruction**

![ISS Encoding Diagram]

CV, bit [24]

Condition code valid. Possible values of this bit are:
- \(00\) The COND field is not valid.
- \(01\) The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to $0b1110$.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to $0b1110$.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to $0b1110$, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to $0b1110$, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

- $0b0$ WFI trapped.
- $0b1$ WFE trapped.

This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating this exception:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2211.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2229.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2244.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- **0b0** The COND field is not valid.
- **0b1** The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is **IMPLEMENTATION DEFINED** whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally **UNKNOWN** value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to **0b1110**.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to **0b1110**.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to **0b1110**, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is **IMPLEMENTATION DEFINED** whether:
  - CV is set to 0 and COND is set to an **UNKNOWN** value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is **IMPLEMENTATION DEFINED** whether the COND field is set to **0b1110**, or to the value of any condition that applied to the instruction.

This field resets to an architecturally **UNKNOWN** value.

**Opc2, bits [19:17]**

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value **0b000**.

This field resets to an architecturally **UNKNOWN** value.
Opc1, bits [16:14]
The Opc1 value from the issued instruction.
For a trapped VMRS access, holds the value 0b111.
This field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]
The CRn value from the issued instruction.
For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.
This field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.
This field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value 0b0000.
This field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0b0 Write to System register space. MCR instruction.
0b1 Read from System register space. MRC or VMRS instruction.
This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b0001:

- Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-2215.
- Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-2216.
- Traps to EL1 of EL0 accesses to Activity Monitors registers on page D1-2217.
- Traps to EL2 of EL1 accesses to virtual memory control registers on page D1-2221.
- Traps to EL2 of EL1 execution of TLB maintenance instructions on page D1-2222.
- Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions on page D1-2223.
- Traps to EL2 of EL1 accesses to the Auxiliary Control Register on page D1-2224.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to \(0b1110\).
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to \(0b1110\), the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.ITS field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \(0b1110\), or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

**Bit [15]**

Reserved, RES0.

**Rt2, bits [14:10]**

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.
This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the first general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.
This field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- \(0b0\) Write to System register space. MCRR instruction.
- \(0b1\) Read from System register space. MRRC instruction.
This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000100\):

- *Traps to EL1 of EL0 accesses to the Generic Timer registers* on page D1-2215.
• Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-2216.
• Traps to EL1 of EL0 accesses to Activity Monitors registers on page D1-2217.
• Traps to EL2 of EL1 accesses to virtual memory control registers on page D1-2221.
• General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-2232.
• Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers on page D1-2236.
• Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2237.
• Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers on page D1-2230.
• Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
• Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

• Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-2213.
• Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
• Traps to EL2 of System register accesses to the trace registers on page D1-2231.
• Trapping System register accesses to Debug ROM registers to EL2 on page D1-2234.
• Traps to EL3 of System register accesses to the trace registers on page D1-2247.
• Trapping System register accesses to powerdown debug registers to EL3 on page D1-2249.
• Trapping general System register accesses to debug registers to EL3 on page D1-2249.

**ISS encoding for an exception from an LDC or STC instruction**

```
24 23  20 19 12 11 10  9  5  4  3  1  0
 |  COND  |  imm8  |  Rn  |  AM  |
    CV   Direction Offset  RES0
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.
COND, bits [23:20]
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]
The immediate value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

Bits [11:10]
Reserved, RES0.

Rn, bits [9:5]
The Rn value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

Offset, bit [4]
Indicates whether the offset is added or subtracted:
0b0 Subtract offset.
0b1 Add offset.
This bit corresponds to the U bit in the instruction encoding.
This field resets to an architecturally UNKNOWN value.

AM, bits [3:1]
Addressing mode. The permitted values of this field are:
0b000 Immediate unindexed.
0b001 Immediate post-indexed.
0b010 Immediate offset.
0b011 Immediate pre-indexed.
0b100 For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110 For a trapped STC instruction, this encoding is reserved.
The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.
Bit [2] in this subfield indicates the instruction form, immediate or literal.
Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.
This field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0b0 Write to memory. STC instruction.
- 0b1 Read from memory. LDC instruction.

This field resets to an architecturally UNKNOWN value.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000110:

- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers** on page D1-2214.
- **Trapping general System register accesses to debug registers to EL2** on page D1-2235.
- **Trapping general System register accesses to debug registers to EL3** on page D1-2249.

### ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include either SVE or support for floating-point and Advanced SIMD, the exception is reported using the EC value 0b000000.

### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.
This field resets to an architecturally **UNKNOWN** value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an **UNKNOWN** value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally **UNKNOWN** value.

**Bits [19:0]**

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- **Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality** on page D1-2214.
- **General trapping to EL2 of accesses to the SIMD and floating-point registers** on page D1-2231.
- **Traps to EL3 of all accesses to the SIMD and floating-point registers** on page D1-2248

**ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ**

<table>
<thead>
<tr>
<th>24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>RES0</strong></td>
</tr>
</tbody>
</table>

**Bits [24:0]**

*When SVE is implemented:*

Reserved, RES0.

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE system registers, ZCR_ELx and ID_AA64ZFR0_EL1.
For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

**ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

24 16 15 0

RES0 imm16

**Bits [24:0]**

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions see *The Illegal Execution state exception on page D1-2182* and *PC alignment checking on page D1-2164*.

*SP alignment checking on page D1-2164* describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from HVC or SVC instruction execution**

24 16 15 0

RES0 imm16

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see *SVC and HVC*.

For A64 instructions, see *SVC and HVC*.
**ISS encoding for an exception from SMC instruction execution in AArch32 state**

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is **RES0**.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:
- **0b0**: The COND field is not valid.
- **0b1**: The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is **RES0**.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to **0b1110**.

For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to **0b1110**.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to **0b1110**, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an **UNKNOWN value**. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to **0b1110**, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is **RES0**.
This field resets to an architecturally UNKNOWN value.

**CCKNOWNPASS, bit [19]**

Indicates whether the instruction might have failed its condition code check.

0b0 The instruction was unconditional, or was conditional and passed its condition code check.

0b1 The instruction was conditional, and might have failed its condition code check.

**Note**

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

This field resets to an architecturally UNKNOWN value.

**Bits [18:0]**

Reserved, RES0.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.

**ISS encoding for an exception from SMC instruction execution in AArch64 state**

\[
\begin{array}{cccc}
24 & 16 & 15 & 0 \\
RES0 & imm16 & \\
\end{array}
\]

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the issued SMC instruction.

This field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.
ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register

**ISS encoding for a IMPLEMENTATION DEFINED exception to EL3**

![ISS Encoding](image)

**IMPLEMENTATION DEFINED, bits [24:0]**

IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from an Instruction Abort**

![ISS encoding diagram]

**Bits [24:13]**

Reserved, RES0.

**SET, bits [12:11]**

Synchronous Error Type. When the RAS Extension is implemented and IFSC is 0b010000, describes the state of the PE after taking the Instruction Abort exception. The possible values of this field are:

- 0b00: Recoverable error (UER).
- 0b10: Uncontainable error (UC).
- 0b11: Restartable error (UEO) or Corrected error (CE).

All other values are reserved.

**Note**

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the IFSC field is not 0b010000.

This field resets to an architecturally UNKNOWN value.

**FnV, bit [10]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0: FAR is valid.
- 0b1: FAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 0b010000. It is RES0 for all other aborts.

This field resets to an architecturally UNKNOWN value.

**EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field resets to an architecturally UNKNOWN value.

**Bit [8]**

Reserved, RES0.
S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- \(0b0\) Fault not on a stage 2 translation for a stage 1 translation table walk.
- \(0b1\) Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is \texttt{RES0}.

This field resets to an architecturally \texttt{UNKNOWN} value.

Bit [6]

Reserved, \texttt{RES0}.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

- \(0b000000\) Address size fault, level 0 of translation or translation table base register
- \(0b000001\) Address size fault, level 1
- \(0b000010\) Address size fault, level 2
- \(0b000011\) Address size fault, level 3
- \(0b000100\) Translation fault, level 0
- \(0b000101\) Translation fault, level 1
- \(0b000110\) Translation fault, level 2
- \(0b000111\) Translation fault, level 3
- \(0b001001\) Access flag fault, level 1
- \(0b001010\) Access flag fault, level 2
- \(0b001011\) Access flag fault, level 3
- \(0b001101\) Permission fault, level 1
- \(0b001110\) Permission fault, level 2
- \(0b001111\) Permission fault, level 3
- \(0b010000\) Synchronous External abort, not on translation table walk
- \(0b010100\) Synchronous External abort, on translation table walk, level 0
- \(0b010101\) Synchronous External abort, on translation table walk, level 1
- \(0b010110\) Synchronous External abort, on translation table walk, level 2
- \(0b010111\) Synchronous External abort, on translation table walk, level 3
- \(0b011000\) Synchronous parity or ECC error on memory access, not on translation table walk
- \(0b011100\) Synchronous parity or ECC error on memory access on translation table walk, level 0
- \(0b011101\) Synchronous parity or ECC error on memory access on translation table walk, level 1
- \(0b011110\) Synchronous parity or ECC error on memory access on translation table walk, level 2
- \(0b011111\) Synchronous parity or ECC error on memory access on translation table walk, level 3
- \(0b110000\) TLB conflict abort
- \(0b110001\) Unsupported atomic hardware update fault, if the implementation includes \texttt{ARMv8.1-TTHM}. Otherwise reserved.

All other values are reserved.

When the RAS Extension is implemented, \(0b011000\), \(0b011100\), \(0b011101\), \(0b011110\), and \(0b011111\), are reserved.

\textbf{Note}

\texttt{ARMv8.2} requires the implementation of the RAS Extension.
For more information about the lookup level associated with a fault, see *The level associated with MMU faults* on page D5-2505.

---

**Note**

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

---

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally **UNKNOWN** value.

**ISS encoding for an exception from a Data Abort**

![ISS encoding diagram]

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:0] is valid.

- **0b0**: No valid instruction syndrome. ISS[23:14] are **RES0**.
- **0b1**: ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- **AArch64** loads and stores of a single general-purpose register (including the register specified with `0b11111`, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback.
- **AArch32** instructions where the instruction:
  - Is an LDR, LDA, LDRRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLH, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using R15 as a source or destination register.

For these cases, ISV is **UNKNOWN** if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

When the RAS Extension is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When the RAS Extension is not implemented, the value of ISV on a synchronous External abort on a stage 2 translation table walk is **IMPLEMENTATION DEFINED**.

This field resets to an architecturally **UNKNOWN** value.

**SAS, bits [23:22]**

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

- **0b00**: **Byte**
0b01    Halfword
0b10    Word
0b11    Doubleword

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

**SSE, bit [21]**

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

0b0    Sign-extension not required.
0b1    Data item must be sign-extended.

For all other operations this bit is 0.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

**SRT, bits [20:16]**

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction. If the exception was taken from an Exception level that is using AArch32 then this is the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

**SF, bit [15]**

Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

0b0    Instruction loads/stores a 32-bit wide register.
0b1    Instruction loads/stores a 64-bit wide register.

--- **Note** ---

This field specifies the register width identified by the instruction, not the Execution state.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

**AR, bit [14]**

Acquire/Release. When ISV is 1, the possible values of this bit are:

0b0    Instruction did not have acquire/release semantics.
0b1    Instruction did have acquire/release semantics.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.
**VNCR, bit [13]**

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

- **0b0** The fault was not generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.
- **0b1** The fault was generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

This field resets to an architecturally **UNKNOWN** value.

**SET, bits [12:11]**

Synchronous Error Type. When the RAS Extension is implemented and DFSC is 0b010000, describes the state of the PE after taking the Data Abort exception. The possible values of this field are:

- **0b00** Recoverable error (UER).
- **0b10** Uncontainable error (UC).
- **0b11** Restartable error (UEO) or Corrected error (CE).

All other values are reserved.

**Note**

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is **RES0** if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010000.

This field resets to an architecturally **UNKNOWN** value.

**FnV, bit [10]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- **0b0** FAR is valid.
- **0b1** FAR is not valid, and holds an **UNKNOWN** value.

This field is valid only if the DFSC code is 0b010000. It is **RES0** for all other aborts.

This field resets to an architecturally **UNKNOWN** value.

**EA, bit [9]**

External abort type. This bit can provide an **IMPLEMENTATION DEFINED** classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field resets to an architecturally **UNKNOWN** value.

**CM, bit [8]**

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- **0b0** The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
- **0b1** The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

This field resets to an architecturally **UNKNOWN** value.
S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0  Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

This field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

0b0  Abort caused by an instruction reading from a memory location.
0b1  Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

• An External abort on an Atomic access.
• A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

This field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

0b000000  Address size fault, level 0 of translation or translation table base register.
0b000001  Address size fault, level 1.
0b000010  Address size fault, level 2.
0b000011  Address size fault, level 3.
0b000100  Translation fault, level 0.
0b000101  Translation fault, level 1.
0b000110  Translation fault, level 2.
0b000111  Translation fault, level 3.
0b001001  Access flag fault, level 1.
0b001010  Access flag fault, level 2.
0b001011  Access flag fault, level 3.
0b001101  Permission fault, level 1.
0b001110  Permission fault, level 2.
0b001111  Permission fault, level 3.
0b010000  Synchronous External abort, not on translation table walk.
0b010001  Synchronous Tag Check fail
0b010100  Synchronous External abort, on translation table walk, level 0.
0b010101  Synchronous External abort, on translation table walk, level 1.
0b010110  Synchronous External abort, on translation table walk, level 2.
0b010111 Synchronous External abort, on translation table walk, level 3.
0b011000 Synchronous parity or ECC error on memory access, not on translation table walk.
0b011100 Synchronous parity or ECC error on memory access on translation table walk, level 0.
0b011101 Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011110 Synchronous parity or ECC error on memory access on translation table walk, level 2.
0b011111 Synchronous parity or ECC error on memory access on translation table walk, level 3.
0b100001 Alignment fault.
0b110001 TLB conflict abort.
0b110001 Unsupported atomic hardware update fault, if the implementation includes ARMv8.1-TTHM. Otherwise reserved.
0b110100 IMPLEMENTATION DEFINED fault (Lockdown).
0b110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).
0b111100 Section Domain Fault, used only for faults reported in the PAR_EL1.
0b111110 Page Domain Fault, used only for faults reported in the PAR_EL1.
All other values are reserved.
When the RAS Extension is implemented, 0b011000, 0b011100, 0b011101, 0b011110, and 0b011111, are reserved.
For more information about the lookup level associated with a fault, see The level associated with MMU faults on page D5-2505.

Note
Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.
This field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]  Reserved, RES0.

TFV, bit [23]  Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions. The possible values of this bit are:
0b0  The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information see Floating-point exceptions and exception traps on page D1-2196.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from a vector instruction.

--- Note ---

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from a vector instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

This field resets to an architecturally UNKNOWN value.

**Bits [22:11]**

Reserved, RES0.

**VECITR, bits [10:8]**

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**IDF, bit [7]**

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Input denormal floating-point exception has not occurred.

0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [6:5]**

Reserved, RES0.

**IXF, bit [4]**

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Inexact floating-point exception has not occurred.

0b1 Inexact floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**UFF, bit [3]**

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Underflow floating-point exception has not occurred.

0b1 Underflow floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**OFF, bit [2]**

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Overflow floating-point exception has not occurred.
0b1        Overflow floating-point exception occurred during execution of the reported instruction.
This field resets to an architecturally UNKNOWN value.

**DZF, bit [1]**

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN.
Otherwise, the possible values of this bit are:
0b0        Divide by Zero floating-point exception has not occurred.
0b1        Divide by Zero floating-point exception occurred during execution of the reported instruction.
This field resets to an architecturally UNKNOWN value.

**IOF, bit [0]**

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN.
Otherwise, the possible values of this bit are:
0b0        Invalid Operation floating-point exception has not occurred.
0b1        Invalid Operation floating-point exception occurred during execution of the reported instruction.
This field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of
  the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of
  the floating-point exception traps.

**ISS encoding for an SError interrupt**

</table>

**IDS, bit [24]**

IMPLEMENTATION DEFINED syndrome. Possible values of this bit are:

0b0        Bits[23:0] of the ISS field holds the fields described in this encoding.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the RAS Extension is not implemented, this means that bits[23:0] of the ISS field are RES0.</td>
</tr>
</tbody>
</table>

0b1        Bits[23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that
can be used to provide additional information about the SError interrupt.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field was previously called ISV.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
Bits [23:14]

Reserved, RES0.

IESB, bit [13]

Implicit error synchronization event.

- **0b0**: The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.
- **0b1**: The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is RES0 if the value returned in the DFSC field is not **0b010001**.

--- **Note**

ARMv8.2 requires the implementation of the RAS Extension and ARMv8.2-IESB.

---

This field resets to an architecturally UNKNOWN value.

AET, bits [12:10]

Asynchronous Error Type.

When the RAS Extension is implemented and DFSC is **0b010001**, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

- **0b000**: Uncontainable error (UC).
- **0b001**: Unrecoverable error (UEU).
- **0b010**: Restartable error (UEO).
- **0b011**: Recoverable error (UER).
- **0b110**: Corrected error (CE).

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

--- **Note**

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

---

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not **0b010001**.

--- **Note**

ARMv8.2 requires the implementation of the RAS Extension.

---

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. When the RAS Extension is implemented, this bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not **0b010001**.
Note

ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

**DFSC, bits [5:0]**

Data Fault Status Code. When the RAS Extension is implemented, possible values of this field are:

- 0b000000 Uncategorized.
- 0b010001 Asynchronous SError interrupt.
- All other values are reserved.

If the RAS Extension is not implemented, this field is RES0.

Note

ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

- 0b0 EX bit is RES0.
- 0b1 EX bit is valid.
See the EX bit description for more information.
This field resets to an architecturally UNKNOWN value.

Bits [23:7]
Reserved, RES0.

EX, bit [6]
Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.
0b0     An instruction other than a Load-Exclusive instruction was stepped.
0b1     A Load-Exclusive instruction was stepped.
If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.
This field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]
Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.
This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see Software Step exceptions on page D2-2329.

ISS encoding for an exception from a Watchpoint exception

Bits [24:14]
Reserved, RES0.

VNCR, bit [13]
Indicates that the watchpoint came from use of VNCR_EL2 register by EL1 code.
0b0     The watchpoint was not generated by the use of VNCR_EL2 by EL1 code.
0b1     The watchpoint was generated by the use of VNCR_EL2 by EL1 code.
This field is 0 in ESR_EL1.
This field resets to an architecturally UNKNOWN value.

Bits [12:9]
Reserved, RES0.

CM, bit [8]
Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:
0b0     The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1     The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.
This field resets to an architecturally UNKNOWN value.

**Bit [7]**

Reserved, RES0.

**WnR, bit [6]**

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

- 0b0 Watchpoint exception caused by an instruction reading from a memory location.
- 0b1 Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance and address translation instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

This field resets to an architecturally UNKNOWN value.

**DFSC, bits [5:0]**

Data Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-2314.

**ISS encoding for an exception from execution of a Breakpoint instruction**

```
<p>| | | | |</p>
<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:16]**

Reserved, RES0.

**Comment, bits [15:0]**

Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT instructions, the comment field is described as the immediate field.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Breakpoint Instruction exceptions* on page D2-2294.

**ISS encoding for an exception from ERET, ERETTA or ERETAB instruction**

```
<p>| | |</p>
<table>
<thead>

```

---

*D12 AArch64 System Register Descriptions*

*D12.2 General system control registers*
This EC value only applies when HCR_EL2.NV is 1.

**Bits [24:2]**

Reserved, RES0.

**ERET, bit [1]**

Indicates whether an ERET or ERETA* instruction was trapped to EL2. Possible values are:

- 0b0 ERET instruction trapped to EL2.
- 0b1 ERETA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

This field resets to an architecturally UNKNOWN value.

**ERETA, bit [0]**

Indicates whether an ERETA or ERETAB instruction was trapped to EL2. Possible values are:

- 0b0 ERETA instruction trapped to EL2.
- 0b1 ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Traps to EL2 for Nested virtualization* on page D1-2240.

**ISS encoding for an exception from Branch Target Identification instruction**

```
  24  2  1  0
   RES0  BTYPE
```

**Bits [24:2]**

Reserved, RES0.

**BTYPE, bits [1:0]**

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see Chapter B1 *The AArch64 Application Level Programmers’ Model*.

**ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0**

```
  24  0
   RES0
```

**Bits [24:0]**

Reserved, RES0.

For more information about generating these exceptions, see:

- *Trap to EL2 of EL0 accesses to Pointer authentication instructions* on page D1-2239.
Accessing the ESR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR_EL2</td>
<td>11</td>
<td>0101</td>
<td>100</td>
<td>000</td>
<td>0010</td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>11</td>
<td>0101</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: - , EL1: - , EL2: n/a , EL3: RW</td>
</tr>
<tr>
<td>ESR_EL2</td>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: - , EL1: - , EL2: ESR_EL1 , EL3: ESR_EL1</td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>ESR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic ESR_EL2 or ESR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If HCR_EL2.{NV2, NV} == {1, 1}, access to ESR_EL2 is redefined to access ESR_EL1 when in EL1. The behavior when in EL3, EL2, or EL0 is unchanged.

If an _EL1 accessor is used, refer to ESR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If \((\text{SCR\_EL3.NS} == 1 \text{ || SCR\_EL3.EEL2} == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& \text{IsUsingAccessor(ESR\_EL2)} \&\& \text{HCR\_EL2.E2H} == 0 \&\& \text{HCR\_EL2.NV} == 1\) then accesses at EL1 are trapped to EL2.

— If \((\text{SCR\_EL3.NS} == 1 \text{ || SCR\_EL3.EEL2} == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& \text{IsUsingAccessor(ESR\_EL2)} \&\& \text{HCR\_EL2.E2H} == 1 \&\& \text{HCR\_EL2.TGE} == 0 \&\& \text{HCR\_EL2.NV} == 1\) then accesses at EL1 are trapped to EL2.
D12.2.38   ESR_EL3, Exception Syndrome Register (EL3)

The ESR_EL3 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ESR_EL3 is a 64-bit register.

**Field descriptions**

The ESR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>63</th>
<th>32</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>ISS</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ESR_EL3 is made UNKNOWN as a result of an exception return from EL3.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL3, the value of ESR_EL3 is UNKNOWN. The value written to ESR_EL3 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Bits [63:32]**

Reserved, RES0.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 0b0000000**

Unknown reason.

See *ISS encoding for exceptions with an unknown reason* on page D12-2848.

**EC == 0b0000001**

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See *ISS encoding for an exception from a WFI or WFE instruction* on page D12-2849.

**EC == 0b0000011**

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See *ISS encoding for an exception from an MCR or MRC access* on page D12-2850.

**EC == 0b0000100**

Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See *ISS encoding for an exception from an MCRR or MRRC access* on page D12-2853.
EC == 0b000101
Trapped MCR or MRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCR or MRC access on page D12-2850.

EC == 0b000110
Trapped LDC or STC access.
The only architected uses of these instruction are:
• An STC to write data to memory from DBGDTRRXint.
• An LDC to read data from memory to DBGDTRTXint.
See ISS encoding for an exception from an LDC or STC instruction on page D12-2855.

EC == 0b000111
Access to SVE, Advanced SIMD, or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.
Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2177.
See ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP on page D12-2857.

EC == 0b001001 From ARMv8.3
Trapped use of a Pointer authentication instruction because HCR_EL2.API == 0 || SCR_EL3.API == 0.
See ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0 on page D12-2877.

EC == 0b001100
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access on page D12-2853.

EC == 0b001110
Illegal Execution state.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2858.

EC == 0b010011
SMC instruction execution in AArch32 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch32 state on page D12-2859.

EC == 0b010101
SVC instruction execution in AArch64 state.
See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2859.

EC == 0b010110
HVC instruction execution in AArch64 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution on page D12-2859.

EC == 0b010111
SMC instruction execution in AArch64 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch64 state on page D12-2861.
EC == 0b011000
Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111, or an exception generated on a read of an ID register.
This includes all instructions that cause exceptions that are part of the encoding space defined in System instruction class encoding overview on page C5-339, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.
See ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register on page D12-2861.

EC == 0b011001
Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC 0b000000.
This EC is defined only if SVE is implemented.
See ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ on page D12-2858.

EC == 0b011111
IMPLEMENTATION DEFINED exception to EL3.
See ISS encoding for a IMPLEMENTATION DEFINED exception to EL3 on page D12-2863.

EC == 0b100000
Instruction Abort from a lower Exception level, that might be using AArch32 or AArch64.
Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from an Instruction Abort on page D12-2863.

EC == 0b100001
Instruction Abort taken without a change in Exception level.
Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from an Instruction Abort on page D12-2863.

EC == 0b100010
PC alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2858.

EC == 0b100100
Data Abort from a lower Exception level, that might be using AArch32 or AArch64.
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data Abort on page D12-2866.

EC == 0b100101
Data Abort taken without a change in Exception level.
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data Abort on page D12-2866.
EC == 0b100110
SP alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2858.

EC == 0b101100
Trapped floating-point exception taken from AArch64 state.
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped floating-point exception on page D12-2870.

EC == 0b101111
SError interrupt.
See ISS encoding for an SError interrupt on page D12-2872.

EC == 0b111100
BRK instruction execution in AArch64 state.
This is reported in ESR_EL3 only if a BRK instruction is executed.
See ISS encoding for an exception from execution of a Breakpoint instruction on page D12-2876.

All other EC values are reserved by ARM, and:
- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7216.

This field resets to an architecturally UNKNOWN value.

**IL, bit [25]**
Instruction Length for synchronous exceptions. Possible values of this bit are:
- 0b0: 16-bit instruction trapped.
- 0b1: An SError interrupt.
  - An Instruction Abort exception.
  - A PC alignment fault exception.
  - An SP alignment fault exception.
  - A Data Abort exception for which the value of the ISV bit is 0.
  - An Illegal Execution state exception.
  - Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
    - 0b0: 16-bit T32 BKPT instruction.
    - 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
  - An exception reported using EC value 0b000000.

This field resets to an architecturally UNKNOWN value.

**ISS, bits [24:0]**
Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.
Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number. For an exception taken from AArch32 state, Mapping of the general-purpose registers between the Execution states on page D1-2264 defines this view of the specified AArch32 register. If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsections describe each ISS format.

**ISS encoding for exceptions with an unknown reason**

<table>
<thead>
<tr>
<th>Bits [24:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
</tbody>
</table>

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
— An HLT instruction when disabled by EDSCR.HDE.

• Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.

• Attempted execution, in Debug state, of:
  — A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  — A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  — A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.

• When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.

• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

• In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.

• An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0b000111.

• When SVE is not implemented, attempted execution of:
  — An SVE instruction.
  — An MSR or MRS instruction to access ZCR_EL1, ZCR_EL2, or ZCR_EL3.

ISS encoding for an exception from a WFI or WFE instruction

<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>COND</td>
<td>RES0</td>
<td>Ti</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CV</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

CV, bit [24]

Condition code valid. Possible values of this bit are:

0b0  The COND field is not valid.
0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to \( 0b1110 \).
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to \( 0b1110 \), the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is implementation defined whether:
  - CV is set to 0 and COND is set to an unknown value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is implementation defined whether the COND field is set to \( 0b1110 \), or to the value of any condition that applied to the instruction. This field resets to an architecturally unknown value.

**Bits [19:1]**

Reserved, RES0.

**T1, bit [0]**

Trapped instruction. Possible values of this bit are:

- \( 0b0 \)  WFI trapped.
- \( 0b1 \)  WFE trapped.

This field resets to an architecturally unknown value.

The following sections describe configuration settings for generating this exception:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions* on page D1-2211.
- *Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions* on page D1-2229.
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-2244.

**ISS encoding for an exception from an MCR or MRC access**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- \( 0b0 \)  The COND field is not valid.
- \( 0b1 \)  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Opc2, bits [19:17]**

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

This field resets to an architecturally UNKNOWN value.

**Opc1, bits [16:14]**

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

This field resets to an architecturally UNKNOWN value.

**CRn, bits [13:10]**

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.

This field resets to an architecturally UNKNOWN value.
CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value \texttt{0b0000}.
This field resets to an architecturally \texttt{UNKNOWN} value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
\begin{itemize}
  \item \texttt{00} Write to System register space. MCR instruction.
  \item \texttt{01} Read from System register space. MRC or VMRS instruction.
\end{itemize}
This field resets to an architecturally \texttt{UNKNOWN} value.

The following sections describe configuration settings for generating exceptions that are reported using EC value \texttt{0b000011}:
\begin{itemize}
  \item Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-2215.
  \item Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-2216.
  \item Traps to EL1 of EL0 accesses to Activity Monitors registers on page D1-2217.
  \item Traps to EL2 of EL1 accesses to virtual memory control registers on page D1-2221.
  \item Traps to EL2 of EL1 execution of TLB maintenance instructions on page D1-2222.
  \item Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions on page D1-2223.
  \item Traps to EL2 of EL1 accesses to the Auxiliary Control Register on page D1-2224.
  \item Traps to EL2 of EL0 and EL1 accesses to lock down, DMA, and TCM operations on page D1-2225.
  \item Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226.
  \item Trapping to EL2 of EL1 accesses to the CPACR_EL1 or CPACR on page D1-2231.
  \item General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-2232.
  \item Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers on page D1-2236.
  \item Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2237.
  \item Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers on page D1-2230.
  \item Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.
  \item Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-2246.
  \item Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
  \item Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.
\end{itemize}

The following sections describe configuration settings for generating exceptions that are reported using EC value \texttt{0b000101}:
\begin{itemize}
  \item Traps to EL1 of EL0 accesses to the trace registers on page D1-2213.
  \item Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
  \item Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226, for trapped accesses to the JIDR.
  \item Traps to EL2 of System register accesses to the trace registers on page D1-2231.
  \item Trapping System register accesses to Debug ROM registers to EL2 on page D1-2234.
• Trapping System register accesses to powerdown debug registers to EL2 on page D1-2234.
• Trapping general System register accesses to debug registers to EL2 on page D1-2235.
• Traps to EL3 of System register accesses to the trace registers on page D1-2247.
• Trapping System register accesses to powerdown debug registers to EL3 on page D1-2249.
• Trapping general System register accesses to debug registers to EL3 on page D1-2249.

Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226 describes configuration settings for generating exceptions that are reported using EC value 0b001000.

**ISS encoding for an exception from an MCRR or MRRC access**

   |COND|Opc1|Rt2|Rt|CRm|

CV, bit [24]
Condition code valid. Possible values of this bit are:

- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.
For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \(0b1110\), or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Bit [15]**

Reserved, RES0.

**Rt2, bits [14:10]**

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.

This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the first general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-2264.

This field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- \(0b0\): Write to System register space. MCRR instruction.
- \(0b1\): Read from System register space. MRRC instruction.

This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000100\):

- **Traps to EL1 of EL0 accesses to the Generic Timer registers** on page D1-2215.
- **Traps to EL1 of EL0 accesses to Performance Monitors registers** on page D1-2216.
- **Traps to EL1 of EL0 accesses to Activity Monitors registers** on page D1-2217.
- **Traps to EL2 of EL1 accesses to virtual memory control registers** on page D1-2221.
- **General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only** on page D1-2232.
- **Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers** on page D1-2236.
- **Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers** on page D1-2237.
- **Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers** on page D1-2230.
- **Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers** on page D1-2250.
- **Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers** on page D1-2246.
The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- **Traps to EL1 of EL0 and EL1 System register accesses to the trace registers** on page D1-2213.
- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers** on page D1-2214.
- **Traps to EL2 of System register accesses to the trace registers** on page D1-2231.

</table>
```

**CV, bit [24]**
Condition code valid. Possible values of this bit are:

- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  — CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the
    SPSR.IT field to determine the condition, if any, of the T32 instruction.
  — CV is set to 1 and COND is set to the condition code for the condition that applied to
    the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a
  trapped conditional instruction only if the instruction passes its condition code check, these
  definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND
  field is set to \(0b1110\), or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**imm8, bits [19:12]**

The immediate value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [11:10]**

Reserved, RES0.

**Rn, bits [9:5]**

The Rn value from the issued instruction, the general-purpose register used for the transfer. The
reported value gives the AArch64 view of the register. See Mapping of the general-purpose
registers between the Execution states on page D1-2264.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC
instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is
UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**Offset, bit [4]**

Indicates whether the offset is added or subtracted:

\(0b0\) Subtract offset.
\(0b1\) Add offset.

This bit corresponds to the U bit in the instruction encoding.

This field resets to an architecturally UNKNOWN value.

**AM, bits [3:1]**

Addressing mode. The permitted values of this field are:

\(0b000\) Immediate unindexed.
\(0b001\) Immediate post-indexed.
\(0b010\) Immediate offset.
\(0b011\) Immediate pre-indexed.
\(0b100\) For a trapped STC instruction or a trapped T32 LDC instruction this encoding is
  reserved.
\(0b110\) For a trapped STC instruction, this encoding is reserved.

The values \(0b101\) and \(0b111\) are reserved. The effect of programming this field to a reserved value is
that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and
memory-mapped registers and translation table entries on page K1-7231.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.

This field resets to an architecturally UNKNOWN value.
Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- **0b0**: Write to memory. STC instruction.
- **0b1**: Read from memory. LDC instruction.

This field resets to an architecturally UNKNOWN value.

The following sections describe the configuration settings for the traps that are reported using EC value `0b000110`:

- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers** on page D1-2214.
- **Trapping general System register accesses to debug registers to EL2** on page D1-2235.
- **Trapping general System register accesses to debug registers to EL3** on page D1-2249.

**ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from CPACR_EL1.FPEN, CPTR_EL2.FPEN or CPTR_ELx.TFP**

```
+---+---+---+---+---+---+---+
| 24| 23| 20| 19|   |   |   |
+---+---+---+---+---+---+---+
| COND| RES0 |
|     |     |
```

CV, bit [24]

Condition code valid. Possible values of this bit are:

- **0b0**: The COND field is not valid.
- **0b1**: The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`. 
A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [19:0]**

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- **Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality** on page D1-2214.
- **General trapping to EL2 of accesses to the SIMD and floating-point registers** on page D1-2231.
- **Traps to EL3 of all accesses to the SIMD and floating-point registers** on page D1-2248

**ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ**

![Image of the trap encoding](image)

**Bits [24:0]**

*When SVE is implemented:*

Reserved, RES0.

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE system registers, ZCR_ELx and ID_AA64ZFR0_EL1.

For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

**ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

![Image of the trap encoding](image)

**Bits [24:0]**

Reserved, RES0.
There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about these exceptions see *The Illegal Execution state exception on page D1-2182* and *PC alignment checking on page D1-2164*.

*SP alignment checking on page D1-2164* describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from HVC or SVC instruction execution**

```
<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>imm16</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.

- If the instruction is conditional, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see *SVC and HVC*.

For A64 instructions, see *SVC and HVC*.

**ISS encoding for an exception from SMC instruction execution in AArch32 state**

```
<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>COND</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

- CV
- CKNOWNPASS

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.
For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid. Possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The COND field is not valid.</td>
</tr>
<tr>
<td>0b1</td>
<td>The COND field is valid.</td>
</tr>
</tbody>
</table>

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The instruction was unconditional, or was conditional and passed its condition code check.</td>
</tr>
<tr>
<td>0b1</td>
<td>The instruction was conditional, and might have failed its condition code check.</td>
</tr>
</tbody>
</table>

Note: In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.
This field resets to an architecturally UNKNOWN value.

**Bits [18:0]**

Reserved, RES0.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.

**ISS encoding for an exception from SMC instruction execution in AArch64 state**

![ISS encoding for an exception from SMC instruction execution in AArch64 state](image)

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the issued SMC instruction.

This field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

*Traps to EL2 of EL1 execution of SMC instructions on page D1-2226* describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and *System calls on page D1-2254* describes the case where these exceptions are trapped to EL3.

**ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register**

![ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state or, when ARMv8.4-IDST is implemented, on a read of an ID register](image)

**Bits [24:22]**

Reserved, RES0.

**Op0, bits [21:20]**

The Op0 value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Op2, bits [19:17]**

The Op2 value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Op1, bits [16:14]**

The Op1 value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

**CRn, bits [13:10]**

The CRn value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the general-purpose register used for the transfer.

This field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0b0: Write access, including MSR instructions.
- 0b1: Read access, including MRS instructions.

This field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see [System instructions](#) on page C4-241 for the encoding values returned by an instruction.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- **In EL1 configurable controls** on page D1-2209.
  - Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-2210.
  - Traps to EL1 of EL0 accesses to the CTR_EL0 on page D1-2211.
  - Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-2212.
  - Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-2212.
  - Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-2213.
  - Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-2214.
  - Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-2215.
  - Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-2216.
  - Traps to EL1 of EL0 accesses to Activity Monitors registers on page D1-2217.

- **In EL2 configurable controls** on page D1-2218.
  - Traps to EL2 of EL1 accesses to virtual memory control registers on page D1-2221.
  - Traps to EL2 of EL0 and EL1 execution of DC ZVA instructions on page D1-2222.
  - Traps to EL2 of EL1 execution of TLB maintenance instructions on page D1-2222.
  - Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions on page D1-2223.
  - Traps to EL2 of EL1 accesses to the Auxiliary Control Register on page D1-2224.
  - Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-2225.
  - Traps to EL2 of EL0 and EL1 accesses to the ID registers on page D1-2226.
  - Trapping to EL2 of EL1 accesses to the CPACR_EL1 or CPACR on page D1-2231.
  - Traps to EL2 of System register accesses to the trace registers on page D1-2231.
  - Trapping System register accesses to Debug ROM registers to EL2 on page D1-2234.
  - Trapping System register accesses to powerdown debug registers to EL2 on page D1-2234.
  - Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers on page D1-2236.
— Trapping general System register accesses to debug registers to EL2 on page D1-2235.
— Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2237.
— Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers on page D1-2230.
— Trap to EL2 of EL1 accesses to Pointer authentication key registers on page D1-2238.
— Traps to EL2 for Nested virtualization on page D1-2240.
— Trap to EL2 of EL1 accesses to AT SIE* instructions on page D1-2241.

— Trap to EL3 configurable controls on page D1-2241.

— Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-2244.
— Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTER, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-2246.
— Traps to EL3 of System register accesses to the trace registers on page D1-2247.
— Trapping System register accesses to powerdown debug registers to EL3 on page D1-2249.
— Trapping general System register accesses to debug registers to EL3 on page D1-2249.
— Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-2250.
— Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers on page D1-2246.

**ISS encoding for a IMPLEMENTATION DEFINED exception to EL3**

```
+-----------+---------+
| IMPLEMENTATION DEFINED |             |
| bits [24:0]             |             |
```

**IMPLEMENTATION DEFINED, bits [24:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from an Instruction Abort**

```
+-----------+-------+-------+-------+-------+-------+-------+-------+
| RES0      | SET   | IFSC  | RES0  | S1PTW | RES0  | EA    | FnV   |
| bits [24:13]|       |       |       |       |       |       |       |
```

**Bits [24:13]**

Reserved, RES0.

**SET, bits [12:11]**

Synchronous Error Type. When the RAS Extension is implemented and IFSC is 0b0100000, describes the state of the PE after taking the Instruction Abort exception. The possible values of this field are:

- 0b00: Recoverable error (UER).
- 0b10: Uncontainable error (UC).
D12 AArch64 System Register Descriptions
D12.2 General system control registers

0b11 Restartable error (UEO) or Corrected error (CE).
All other values are reserved.

--- Note ---
Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:
• The RAS Extension is not implemented.
• The value returned in the IFSC field is not 0b010000.
This field resets to an architecturally UNKNOWN value.

FnV, bit [10]
FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.
0b0 FAR is valid.
0b1 FAR is not valid, and holds an UNKNOWN value.
This field is only valid if the IFSC code is 0b010000. It is RES0 for all other aborts.
This field resets to an architecturally UNKNOWN value.

EA, bit [9]
External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.
For any abort other than an External abort this bit returns a value of 0.
This field resets to an architecturally UNKNOWN value.

Bit [8]
Reserved, RES0.

S1PTW, bit [7]
For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:
0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.
For any abort other than a stage 2 fault this bit is RES0.
This field resets to an architecturally UNKNOWN value.

Bit [6]
Reserved, RES0.

IFSC, bits [5:0]
Instruction Fault Status Code. Possible values of this field are:
0b000000 Address size fault, level 0 of translation or translation table base register
0b000001 Address size fault, level 1
0b000010 Address size fault, level 2
0b000011 Address size fault, level 3
0b000100 Translation fault, level 0
0b000101 Translation fault, level 1
0b000110 Translation fault, level 2
0b000111 Translation fault, level 3
0b001001 Access flag fault, level 1
0b001010 Access flag fault, level 2
0b001011 Access flag fault, level 3
0b001101 Permission fault, level 1
0b001110 Permission fault, level 2
0b001111 Permission fault, level 3
0b010000 Synchronous External abort, not on translation table walk
0b010100 Synchronous External abort, on translation table walk, level 0
0b010101 Synchronous External abort, on translation table walk, level 1
0b010110 Synchronous External abort, on translation table walk, level 2
0b010111 Synchronous External abort, on translation table walk, level 3
0b011000 Synchronous parity or ECC error on memory access, not on translation table walk
0b011100 Synchronous parity or ECC error on memory access on translation table walk, level 0
0b011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
0b011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
0b011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
0b110000 TLB conflict abort
0b110001 Unsupported atomic hardware update fault, if the implementation includes ARMv8.1-TTHM. Otherwise reserved.

All other values are reserved.

When the RAS Extension is implemented, 0b011000, 0b011100, 0b011101, 0b011110, and 0b011111, are reserved.

_____ Note _____

ARMv8.2 requires the implementation of the RAS Extension.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on page D5-2505.

_____ Note _____

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally UNKNOWN value.
**ISS encoding for an exception from a Data Abort**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISV</td>
<td>Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:0] is valid.</td>
</tr>
<tr>
<td>SSE</td>
<td>Syntrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.</td>
</tr>
<tr>
<td>SF</td>
<td></td>
</tr>
<tr>
<td>AR</td>
<td></td>
</tr>
<tr>
<td>VNCR</td>
<td></td>
</tr>
</tbody>
</table>

**ISV, bit [24]**

- **0** — No valid instruction syndrome. ISS[23:14] are RES0.
- **1** — ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
  - Is an LDR, LDA, LDRT, LDRSH, LDRHT, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDA, LDRBT, STR, STL, STRT, STRH, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using R15 as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

When the RAS Extension is implemented, ISV is 0 for any synchronous External abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When the RAS Extension is not implemented, the value of ISV on a synchronous External abort on a stage 2 translation table walk is IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**SAS, bits [23:22]**

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

- **0b00** — Byte
- **0b01** — Halfword
- **0b10** — Word
- **0b11** — Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

This field resets to an architecturally UNKNOWN value.
SSE, bit [21]
Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

\[0b0\] Sign-extension not required.
\[0b1\] Data item must be sign-extended.

For all other operations this bit is 0.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

SRT, bits [20:16]
Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction. If the exception was taken from an Exception level that is using AArch32 then this is the AArch64 view of the register. See Mapping of the general-purpose registers between the Execution states on page D1-2264.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

SF, bit [15]
Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

\[0b0\] Instruction loads/stores a 32-bit wide register.
\[0b1\] Instruction loads/stores a 64-bit wide register.

--- **Note** ---
This field specifies the register width identified by the instruction, not the Execution state.

--- ---
This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

AR, bit [14]
Acquire/Release. When ISV is 1, the possible values of this bit are:

\[0b0\] Instruction did not have acquire/release semantics.
\[0b1\] Instruction did have acquire/release semantics.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.
This field is **RES0** when the value of ISV is 0.
This field resets to an architecturally **UNKNOWN** value.

VNCR, bit [13]
Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

\[0b0\] The fault was not generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.
\[0b1\] The fault was generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.
This field resets to an architecturally **UNKNOWN** value.
SET, bits [12:11]

Synchronous Error Type. When the RAS Extension is implemented and DFSC is 0b010000, describes the state of the PE after taking the Data Abort exception. The possible values of this field are:

- 0b0: Recoverable error (UER).
- 0b10: Uncontainable error (UC).
- 0b11: Restartable error (UEO) or Corrected error (CE).

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010000.

This field resets to an architecturally UNKNOWN value.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0: FAR is valid.
- 0b1: FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- 0b0: The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
- 0b1: The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

This field resets to an architecturally UNKNOWN value.

SIPTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0b0: Fault not on a stage 2 translation for a stage 1 translation table walk.
- 0b1: Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

This field resets to an architecturally UNKNOWN value.
**WnR, bit [6]**

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

- 0b0  Abort caused by an instruction reading from a memory location.
- 0b1  Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is **UNKNOWN** for:
- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

This field resets to an architecturally **UNKNOWN** value.

**DFSC, bits [5:0]**

Data Fault Status Code. Possible values of this field are:

- 0b000000  Address size fault, level 0 of translation or translation table base register.
- 0b000001  Address size fault, level 1.
- 0b000010  Address size fault, level 2.
- 0b000011  Address size fault, level 3.
- 0b000100  Translation fault, level 0.
- 0b000101  Translation fault, level 1.
- 0b000110  Translation fault, level 2.
- 0b000111  Translation fault, level 3.
- 0b001000  Access flag fault, level 1.
- 0b001001  Access flag fault, level 2.
- 0b001010  Access flag fault, level 3.
- 0b001100  Permission fault, level 1.
- 0b001101  Permission fault, level 2.
- 0b001111  Permission fault, level 3.
- 0b010000  Synchronous External abort, not on translation table walk.
- 0b010001  Synchronous Tag Check fail
- 0b010100  Synchronous External abort, on translation table walk, level 0.
- 0b010101  Synchronous External abort, on translation table walk, level 1.
- 0b010110  Synchronous External abort, on translation table walk, level 2.
- 0b010111  Synchronous External abort, on translation table walk, level 3.
- 0b011000  Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b011100  Synchronous parity or ECC error on memory access on translation table walk, level 0.
- 0b011101  Synchronous parity or ECC error on memory access on translation table walk, level 1.
- 0b011110  Synchronous parity or ECC error on memory access on translation table walk, level 2.
- 0b011111  Synchronous parity or ECC error on memory access on translation table walk, level 3.
- 0b100001  Alignment fault.
0b110000 TLB conflict abort.
0b110001 Unsupported atomic hardware update fault, if the implementation includes ARMv8.1-TTHM. Otherwise reserved.
0b110100 IMPLEMENTATION DEFINED fault (Lockdown).
0b110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).
0b111101 Section Domain Fault, used only for faults reported in the PAR_EL1.
0b111110 Page Domain Fault, used only for faults reported in the PAR_EL1.

All other values are reserved.

When the RAS Extension is implemented, 0b011000, 0b011100, 0b011101, 0b011110, and 0b011111, are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on page D5-2505.*

--- Note ---
Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

--- ---
If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a trapped floating-point exception**

![ISS encoding diagram]

**Bit [24]**
Reserved, RES0.

**TFV, bit [23]**
Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions. The possible values of this bit are:

0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.

0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information see *Floating-point exceptions and exception traps on page D1-2196.*

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from a vector instruction.
### Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from a vector instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

This field resets to an architecturally UNKNOWN value.

**Bits [22:11]**

Reserved, RES0.

**VECITR, bits [10:8]**

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**IDF, bit [7]**

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Input denormal floating-point exception has not occurred.
- 0b1: Input denormal floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [6:5]**

Reserved, RES0.

**IXF, bit [4]**

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Inexact floating-point exception has not occurred.
- 0b1: Inexact floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**UFF, bit [3]**

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Underflow floating-point exception has not occurred.
- 0b1: Underflow floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.

**OFF, bit [2]**

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0: Overflow floating-point exception has not occurred.
- 0b1: Overflow floating-point exception occurred during execution of the reported instruction.

This field resets to an architecturally UNKNOWN value.
DZF, bit [1]
Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
\[0b0\] Divide by Zero floating-point exception has not occurred.
\[0b1\] Divide by Zero floating-point exception occurred during execution of the reported instruction.
This field resets to an architecturally UNKNOWN value.

IOF, bit [0]
Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
\[0b0\] Invalid Operation floating-point exception has not occurred.
\[0b1\] Invalid Operation floating-point exception occurred during execution of the reported instruction.
This field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:
• From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
• From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

**ISS encoding for an SError interrupt**

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

**IDS, bit [24]**
IMPLEMENTATION DEFINED syndrome. Possible values of this bit are:
\[0b0\] Bits[23:0] of the ISS field holds the fields described in this encoding.
\[0b1\] Bits[23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

This field was previously called ISV.
This field resets to an architecturally UNKNOWN value.

**Bits [23:14]**
Reserved, RES0.
IESB, bit [13]

Implicit error synchronization event.

0b0  The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1  The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

This field is RES0 if the value returned in the DFSC field is not 0b010001.

——— Note ————

ARMv8.2 requires the implementation of the RAS Extension and ARMv8.2-IESB.

——— Note ————

This field resets to an architecturally UNKNOWN value.

AET, bits [12:10]

Asynchronous Error Type.

When the RAS Extension is implemented and DFSC is 0b010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

0b000  Uncontainable error (UC).
0b001  Unrecoverable error (UEU).
0b010  Restartable error (UEO).
0b011  Recoverable error (UER).
0b110  Corrected error (CE).

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

——— Note ————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

——— Note ————

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010001.

——— Note ————

ARMv8.2 requires the implementation of the RAS Extension.

——— Note ————

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. When the RAS Extension is implemented, this bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field is RES0 if either:
- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 0b010001.

——— Note ————

ARMv8.2 requires the implementation of the RAS Extension.
This field resets to an architecturally UNKNOWN value.

**Bits [8:6]**

Reserved, RES0.

**DFSC, bits [5:0]**

Data Fault Status Code. When the RAS Extension is implemented, possible values of this field are:
- 0b000000  Uncategorized.
- 0b010001  Asynchronous SError interrupt.

All other values are reserved.

If the RAS Extension is not implemented, this field is RES0.

--- **Note** ---

ARMv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a Breakpoint or Vector Catch debug exception**

<table>
<thead>
<tr>
<th></th>
<th>24</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RES0</td>
<td>IFSC</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions:

- For exceptions from AArch64, see *Breakpoint exceptions* on page D2-2296.
- For exceptions from AArch32, see *Breakpoint exceptions* on page G2-5366 and *Vector Catch exceptions* on page G2-5405.

**ISS encoding for an exception from a Software Step exception**

<table>
<thead>
<tr>
<th></th>
<th>24</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RES0</td>
<td>IFSC</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:
- 0b0  EX bit is RES0.
- 0b1  EX bit is valid.

See the EX bit description for more information.

This field resets to an architecturally UNKNOWN value.
### Bits [23:7]

Reserved, RES0.

### EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

- **0b0**: An instruction other than a Load-Exclusive instruction was stepped.
- **0b1**: A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available. This field resets to an architecturally UNKNOWN value.

### IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception. This field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Software Step exceptions on page D2-2329*.

### ISS encoding for an exception from a Watchpoint exception

![ISS encoding diagram](image)

**Bits [24:14]**

Reserved, RES0.

**VNCR, bit [13]**

Indicates that the watchpoint came from use of VNCR_EL2 register by EL1 code.

- **0b0**: The watchpoint was not generated by the use of VNCR_EL2 by EL1 code.
- **0b1**: The watchpoint was generated by the use of VNCR_EL2 by EL1 code.

This field is 0 in ESR_EL1. This field resets to an architecturally UNKNOWN value.

**Bits [12:9]**

Reserved, RES0.

**CM, bit [8]**

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance or address translation instruction:

- **0b0**: The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
- **0b1**: The Watchpoint exception was generated by either the execution of a cache maintenance instruction or by a synchronous Watchpoint exception on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

This field resets to an architecturally UNKNOWN value.
Bit [7]
Reserved, RES0.

WnR, bit [6]
Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing
to a memory location, or by an instruction reading from a memory location. The possible values of
this bit are:
0b0 Watchpoint exception caused by an instruction reading from a memory location.
0b1 Watchpoint exception caused by an instruction writing to a memory location.
For Watchpoint exceptions on cache maintenance and address translation instructions, this bit
always returns a value of 1.
For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location
would have generated the Watchpoint exception, otherwise it is set to 1.
If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates
the Watchpoint exception.
This field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]
Data Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.
This field resets to an architecturally UNKNOWN value.
For more information about generating these exceptions, see Watchpoint exceptions on page D2-2314.

ISS encoding for an exception from execution of a Breakpoint instruction

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Comment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [24:16]
Reserved, RES0.

Comment, bits [15:0]
Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT
instructions, the comment field is described as the immediate field.
This field resets to an architecturally UNKNOWN value.
For more information about generating these exceptions, see Breakpoint Instruction exceptions on page D2-2294.

ISS encoding for an exception from ERET, ERETA or ERETAB instruction

<table>
<thead>
<tr>
<th>24</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ERETA</td>
<td>ERET</td>
<td></td>
</tr>
</tbody>
</table>

This EC value only applies when HCR_EL2.NV is 1.

Bits [24:2]
Reserved, RES0.
ERET, bit [1]
Indicates whether an ERET or ERETA* instruction was trapped to EL2. Possible values are:
0b0 ERET instruction trapped to EL2.
0b1 ERETA or ERETA* instruction trapped to EL2.
If this bit is 0, the ERETA field is RES0.
This field resets to an architecturally UNKNOWN value.

ERETA, bit [0]
Indicates whether an ERETA or ERETA* instruction was trapped to EL2. Possible values are:
0b0 ERETA instruction trapped to EL2.
0b1 ERETA* instruction trapped to EL2.
When the ERET field is 0, this bit is RES0.
This field resets to an architecturally UNKNOWN value.
For more information about generating these exceptions, see Traps to EL2 for Nested virtualization on page D1-2240.

**ISS encoding for an exception from Branch Target Identification instruction**

![ISS encoding](image)

Bits [24:2]
Reserved, RES0.

BTYPE, bits [1:0]
This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.
For more information about generating these exceptions, see Chapter B1 The AArch64 Application Level Programmers’ Model.

**ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0**

![ISS encoding](image)

Bits [24:0]
Reserved, RES0.
For more information about generating these exceptions, see:
- Trap to EL2 of EL0 accesses to Pointer authentication instructions on page D1-2239.
- Trap to EL3 accesses to Pointer authentication instructions on page D1-2252.

**Accessing the ESR_EL3**
This register can be written using MSR (register) with the following syntax:
MSR `<systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS `<Xt>, `<systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>`&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR_EL3</td>
<td>11</td>
<td>0101</td>
<td>110</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.39 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

**Purpose**

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL1.

**Configurations**

AArch64 System register FAR_EL1[31:0] is architecturally mapped to AArch32 System register DFAR[31:0] (NS).

AArch64 System register FAR_EL1[63:32] is architecturally mapped to AArch32 System register IFAR[31:0] (NS).

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

FAR_EL1 is a 64-bit register.

**Field descriptions**

The FAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Faulting Virtual Address for synchronous exceptions taken to EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>?</td>
</tr>
<tr>
<td>62</td>
<td>?</td>
</tr>
<tr>
<td>31-0</td>
<td>0</td>
</tr>
</tbody>
</table>

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). ESR_EL1.EM holds the EC value for the exception.

For a synchronous External abort, if the VA that generated the abort was from an address range for which TCR_ELx.TBI[<0|1>] == 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL1 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL1.EM is 0, and the FAR_EL1 is UNKNOWN if ESR_EL1.EM is 1.

For all other exceptions taken to EL1, the FAR_EL1 is UNKNOWN.

If a memory fault that sets FAR_EL1 is generated from a cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL1 is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are 0x00000001:

- The faulting address was generated by a load or store instruction that sequentially incremented from address 0xffffffff. Such a load or store is CONSTRAINED UNPREDICTABLE. See Out of range VA on page K1-7203.

- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see Address tagging in AArch64 state on page D5-2386.
The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL1 is made UNKNOWN on an exception return from EL1. This field resets to an architecturally UNKNOWN value.

Accessing the FAR_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <xt>

This register can be read using MRS with the following syntax:

MRS <xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAR_EL1</td>
<td>11</td>
<td>0110</td>
<td>000</td>
<td>000</td>
<td>0000</td>
</tr>
<tr>
<td>FAR_EL12</td>
<td>11</td>
<td>0110</td>
<td>101</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW</td>
</tr>
<tr>
<td>FAR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>FAR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>FAR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
</tbody>
</table>
When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic FAR_EL1 or FAR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If `IsUsingAccessor(FAR_EL1)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TRVM == 1`, then read accesses at EL1 are trapped to EL2.
- If `(HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0)` && `IsUsingAccessor(FAR_EL12)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TRVM == 1`, then read accesses at EL1 are trapped to EL2.
- If `IsUsingAccessor(FAR_EL1)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.
- If `(HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0)` && `IsUsingAccessor(FAR_EL12)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.
- If `IsUsingAccessor(FAR_EL1)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TVM == 1`, then read accesses at EL1 are trapped to EL2.
- If `(HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0)` && `IsUsingAccessor(FAR_EL12)` && `(SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1)` && `IsUsingAArch64(EL2)` && `HCR_EL2.E2H == 0` && `HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.
D12.2.40 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL2.

Configurations

AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register HDFAR[31:0].
AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register HIFAR[31:0].
AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register DFAR[31:0] (S) when IsExceptionLevelImplemented(EL2).
AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register IFAR[31:0] (S) when IsExceptionLevelImplemented(EL2).
If EL2 is not implemented, this register is RES0 from EL3.
This register has no effect if EL2 is not enabled in the current Security state.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

The FAR_EL2 bit assignments are:

Faulting Virtual Address for synchronous exceptions taken to EL2

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). ESR_EL2.EC holds the EC value for the exception.
For a synchronous External abort, if the VA that generated the abort was from an address range for which TCR_ELx.TBI{<0|1>} == 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL2 are UNKNOWN.
For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL2.FnV is 0, and the FAR_EL2 is UNKNOWN if ESR_EL2.FnV is 1.
For all other exceptions taken to EL2, the FAR_EL2 is UNKNOWN.
If a memory fault that sets FAR_EL2 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.
If the exception that updates FAR_EL2 is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_EL2 are 0x00000001:

• The faulting address was generated by a load or store instruction that sequentially incremented from address 0xffffffff. Such a load or store instruction is CONSTRAINED UNPREDICTABLE. See Out of range VA on page K1-7203.
The implementation treats such incrementing as setting bit[32] of the virtual address to 1. For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see Address tagging in AArch64 state on page D5-2386.

**Note**
The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL2 is made **UNKNOWN** on an exception return from EL2. This field resets to an architecturally **UNKNOWN** value.

### Accessing the FAR_EL2

This register can be written using MSR (register) with the following syntax:

```markdown
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```markdown
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAR_EL2</td>
<td>11</td>
<td>0110</td>
<td>100</td>
<td>000</td>
<td>0000</td>
</tr>
<tr>
<td>FAR_EL1</td>
<td>11</td>
<td>0110</td>
<td>000</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>FAR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SC_EL3.EEL2 == 0</td>
<td>n/a</td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>FAR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SC_EL3.EEL2 == 0</td>
<td>FAR_EL1</td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic FAR_EL2 or
FAR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If HCR_EL2.{NV2, NV} == {1, 1}, access to FAR_EL2 is redefined to access FAR_EL1 when in EL1. The behavior
when in EL3, EL2, or EL0 is unchanged.

If an _EL1 accessor is used, refer to FAR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for
exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & IsUsingAccessor(FAR_EL2) & HCR_EL2.E2H == 0 &
  HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & IsUsingAccessor(FAR_EL2) &
  HCR_EL2.E2H == 1 & HCR_EL2.TGE == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.41 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

**Purpose**
Holds the faulting Virtual Address for all synchronous Instruction or Data Abort and PC alignment fault exceptions that are taken to EL3.

**Configurations**
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
FAR_EL3 is a 64-bit register.

**Field descriptions**
The FAR_EL3 bit assignments are:

| Bit 63 | Bit 62 | Bit 61 | Bit 60 | Bit 59 | Bit 58 | Bit 57 | Bit 56 | Bit 55 | Bit 54 | Bit 53 | Bit 52 | Bit 51 | Bit 50 | Bit 49 | Bit 48 | Bit 47 | Bit 46 | Bit 45 | Bit 44 | Bit 43 | Bit 42 | Bit 41 | Bit 40 | Bit 39 | Bit 38 | Bit 37 | Bit 36 | Bit 35 | Bit 34 | Bit 33 | Bit 32 | Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |

| 63     | ??     | ??     | ??     | 62     | 61     | 60     | 59     | 58     | 57     | 56     | 55     | 54     | 53     | 52     | 51     | 50     | 49     | 48     | 47     | 46     | 45     | 44     | 43     | 42     | 41     | 40     | 39     | 38     | 37     | 36     | 35     | 34     | 33     | 32     | 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     | 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      |

Faulting Virtual Address for synchronous exceptions taken to EL3

Bits [63:0]
Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR_EL3 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), and PC alignment faults (EC 0x22). ESR_EL3.EC holds the EC value for the exception.

For a synchronous External abort, if the VA that generated the abort was from an address range for which TCR_ELx.TBI{<0|1>} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR_EL3 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL3.FnV is 0, and the FAR_EL3 is UNKNOWN if ESR_EL3.FnV is 1.

For all other exceptions taken to EL3, the FAR_EL3 is UNKNOWN.

If a memory fault that sets FAR_EL3 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL3 is taken from an Exception Level using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_EL3 are 0x00000001:

- The faulting address was generated by a load or store instruction that sequentially incremented from address 0xFFFFFFFF. Such a load or store instruction is CONSTRAINED UNPREDICTABLE. See Out of range VA on page K1-7203.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see Address tagging in AArch64 state on page D5-2386.

**Note**
The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL3 is made UNKNOWN on an exception return from EL3.
This field resets to an architecturally UNKNOWN value.

Accessing the FAR_EL3

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAR_EL3</td>
<td>11</td>
<td>0110</td>
<td>110</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.42 FPEXC32_EL2, Floating-Point Exception Control register

The FPEXC32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register FPEXC from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**

AArch64 System register FPEXC32_EL2[31:0] is architecturally mapped to AArch32 System register FPEXC[31:0].

If EL1 cannot use AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturallyUNKNOWN values.

**Attributes**

FPEXC32_EL2 is a 64-bit register.

**Field descriptions**

The FPEXC32_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31</td>
<td>EX, bit [31] Exception bit. In ARMv8, this bit is RAZ/WI. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>EN, bit [30] Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:</td>
</tr>
<tr>
<td></td>
<td>- VMSR accesses to the FPEXC or FPSID.</td>
</tr>
<tr>
<td></td>
<td>- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.</td>
</tr>
<tr>
<td></td>
<td>- 0b0 Accesses to the FPSR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.</td>
</tr>
<tr>
<td></td>
<td>- 0b1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.</td>
</tr>
</tbody>
</table>
Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- **CPACR.cp10**, or, if executing at EL0, **CPACR_EL1.FPEN**.
- **FPEXC.EN**.
- If executing in Non-secure state:
  - **HCPTR.TCP10**, or if EL2 is using AArch64, **CPTR_EL2.TFP**.
  - **NSACR.cp10**, or if EL3 is using AArch64, **CPTR_EL3.TFP**.
- For Advanced SIMD instructions only:
  - **CPACR.ASEDIS**.
  - If executing in Non-secure state, **HCPTR.TASE** and **NSACR.NSTRCDIS**.

See the descriptions of the controls for more information.

—— Note ——

When executing at EL0 using AArch32:

- If EL1 is using AArch64 then behavior is as if the value of FPEXC.EN is 1.
- If EL2 is using AArch64 and enabled in the current Security state, and the value of **HCR_EL2.{RW, TGE}** is {1, 1} then behavior is as if the value of FPEXC.EN is 1.
- If EL2 is using AArch64 and enabled in the current Security state, and the value of **HCR_EL2.{RW, TGE}** is {0, 1} then it is IMPLEMENTATION DEFINED whether the behavior is:
  - As if the value of FPEXC.EN is 1.
  - Determined by the value of FPEXC32_EL2.EN, as described in this field description. However, ARM deprecates using the value of FPEXC32_EL2.EN to determine behavior.

This field resets to an architecturally UNKNOWN value.

**DEX, bit [29]**

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr() returning TRUE. This field also indicates whether the FPEXC32_EL2.TFV field is valid.

The meaning of this bit is:

- **0**: The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr(). If FPEXC32_EL2.TFV is RW then it is invalid and UNKNOWN. If FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.

- **1**: The exception was generated during the execution of an unallocated encoding. FPEXC32_EL2.TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the AArch32 FPSCR.\{(Stride, Len)\} fields as RAZ, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**FP2V, bit [28]**

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

This field resets to an architecturally UNKNOWN value.
VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

0b0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR. {Stride, Len} was non-zero. If the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.

0b1 FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements FPSCR. {Stride, Len} as RAZ, this bit is RAO/WI.

This field resets to an architecturally UNKNOWN value.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is RES1.

This field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0b0 Input Denormal exception has not occurred.

0b1 Input Denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

Note

A half-precision floating-point value that is flushed to zero because the value of FPSCR.FZ16 is 1 does not generate an Input Denormal exception.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.
IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

- 0b0: Inexact exception has not occurred.
- 0b1: Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

- 0b0: Underflow exception has not occurred.
- 0b1: Underflow exception has occurred.

Underflow trapped exceptions can occur:
- On half-precision data-processing instructions only when FPSCR.FZ16 is 0.
- Otherwise only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

- 0b0: Overflow exception has not occurred.
- 0b1: Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

- 0b0: Divide by Zero exception has not occurred.
- 0b1: Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.
IOF, bit [0]
Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSR.IOE was 1:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Invalid Operation exception has not occurred.</td>
</tr>
<tr>
<td>0b1</td>
<td>Invalid Operation exception has occurred.</td>
</tr>
</tbody>
</table>

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

Accessing the FPEXC32_EL2

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191](#). Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && CPTR_EL2.TFP == 1, then accesses at EL2 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && CPTR_EL2.FPEN == 0, then accesses at EL2 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && CPTR_EL2.FPEN == 10, then accesses at EL2 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && CPTR_EL2.FPEN == 0, then accesses at EL2 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && CPTR_EL2.FPEN == 10, then accesses at EL2 are trapped to EL2.
- If IsUsingAArch64(EL3) && CPTR_EL3.TFP == 1, then accesses at EL2 or EL3 are trapped to EL3.
D12.2.43 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

**Purpose**

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of EL1 or EL0 operation.

--- Note ---

ARM recommends that the values in this register do not cause unnecessary traps to EL2 when HCR_EL2.{E2H, TGE} == \{1, 1\}.

**Configurations**

AArch64 System register HACR_EL2[31:0] is architecturally mapped to AArch32 System register HACR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACR_EL2 is a 64-bit register.

**Field descriptions**

The HACR_EL2 bit assignments are:

| 63 | 0 |
|-------------------------|
| IMPLEMENTATION DEFINED |

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the HACR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>

<td>11</td>
<td>0001</td>
<td>100</td>
<td>111</td>
<td>0001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.44 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

**Configurations**

AArch64 System register HCR_EL2[31:0] is architecturally mapped to AArch32 System register HCR[31:0].

AArch64 System register HCR_EL2[63:32] is architecturally mapped to AArch32 System register HCR2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**RW fields in this register reset to architecturally UNKNOWN values.**

**Attributes**

HCR_EL2 is a 64-bit register.

**Field descriptions**

The HCR_EL2 bit assignments are:

```
| 63  | 48  | 47  | 46  | 45  | 44  | 43  | 42  | 41  | 40  | 39  | 38  | 37  | 36  | 35  | 34  | 33  | 32  | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

**Bits [63:48]**

Reserved, RES0.
FIEN, bit [47]

*From ARMv8.4:*

Fault Injection Enable. Unless this bit is set to 1, accesses to the ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1 registers from EL1 generate a Trap exception to EL2, when EL2 is enabled in the current Security state.

0b0  Accesses to the specified registers from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

0b1  This control does not cause any instructions to be trapped.

If EL2 is disabled in the current Security state, the *Effective value* of HCR_EL2.FIEN is 0b1.

If the RAS Common Fault Injection Model Extension is not implemented, this field is RES0.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

FWB, bit [46]

*When ARMv8.4-S2FWB is implemented:*

Defines the combined cacheability attributes in a 2 stage translation regime.

0b0  When this bit is 0, then:

- The combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the ARMv8.0 architecture. For more information see *Combining the stage 1 and stage 2 attributes, EL1&0 translation regime* on page D5-2482
- The encoding of the stage 2 memory type and cacheability attributes in bits[5:2] of the stage 2 page or block descriptors are as described in the ARMv8.0 architecture.

0b1  When this bit is 1, then:

- Bit[5] of stage 2 page or block descriptor is RES0.
- When bit[4] of stage 2 page or block descriptor is 1 and when:
  - Bits[3:2] of stage 2 page or block descriptor are 0b11, the resultant memory type and inner or outer cacheability attribute is the same as the stage 1 memory type and inner or outer cacheability attribute.
  - Bits[3:2] of stage 2 page or block descriptor are 0b10, the resultant memory type and attribute is Normal Write-Back.
  - Bits[3:2] of stage 2 page or block descriptor are 0b0x, the resultant memory type will be Normal Non-cacheable except where the stage 1 memory type was Device->attr< the resultant memory type will be Device->attr<
- When bit[4] of stage 2 page or block descriptor is 0 the memory type is Device, and when:
  - Bits[3:2] of stage 2 page or block descriptor are 0b00, the resultant memory type is Device-nGnRnE.
  - Bits[3:2] of stage 2 page or block descriptor are 0b01, the resultant memory type is Device-nGnRE.
  - Bits[3:2] of stage 2 page or block descriptor are 0b10, the resultant memory type is Device-nGRE.
  - Bits[3:2] of stage 2 page or block descriptor are 0b11, the resultant memory type is Device-GRE.
- If the stage 1 translation specifies a cacheable memory type, then the stage 1 cache allocation hint is applied to the final cache allocation hint where the final memory type is cacheable.
If the stage 1 translation does not specify a cacheable memory type, then if the final memory type is cacheable, it is treated as read allocate, write allocate.

In Secure state, this bit applies to both the Secure stage 2 translation and the Non-secure stage 2 translation.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**NV2, bit [45]**

*When ARMv8.4-NV is implemented:*

Nested Virtualization. Changes the behaviors of HCR_EL2.{NV, NV1} to provide a mechanism for hardware to transform reads and writes from System registers into reads and writes from memory.

0b0 This bit has no effect on the behavior of HCR_EL2.{NV, NV1}.

0b1 Redefines behavior of HCR_EL2{NV, NV1} to enable:

  * Transformation of read/writes to registers into read/writes to memory.
  * Redirection of EL2 registers to EL1 registers.

When this bit is 0, the behavior of HCR_EL2.{NV, NV1} is as defined for ARMv8.3-NV.

When this bit is 1, then any exception taken from EL1 and taken to EL1 causes SPSR_EL1.M[3:2] to be set to 0b10 and not 0b01.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**AT, bit [44]**

*When ARMv8.3-NV is implemented:*

Address Translation. EL1 execution of the following address translation instructions is trapped to EL2, when EL2 is enabled in the current Security state:

AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 execution of the specified instructions is trapped to EL2.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**NV1, bit [43]**

*When ARMv8.4-NV is implemented:*

Nested Virtualization.

0b0 If HCR_EL2.{NV, NV2} are both 1, accesses executed from EL1 to implemented EL12, EL02, or EL2 registers are transformed to loads and stores. If HCR_EL2.NV2 is 0 or HCR_EL2.{NV, NV2} == {0, 1}, this control does not cause any instructions to be trapped.

0b1 If HCR_EL2.NV2 is 1, accesses executed from EL1 to implemented EL2 registers are transformed to loads and stores. If HCR_EL2.NV2 is 0, EL1 accesses to VBAR_EL1, ELR_EL1, and SPSR_EL1, are trapped to EL2, when EL2 is enabled in the current Security state.

If HCR_EL2.NV2 is 1, the value of HCR_EL2.NV1 defines which EL1 register accesses are transformed to loads and stores. These transformed accesses have priority over the trapping of registers.
The trapping of EL1 registers caused by other control bits has priority over the transformation of these accesses.

If a register is specified that is not implemented by an implementation, then access to that register is treated as unallocated.

For the list of registers affected, see Enhanced support for nested virtualization on page D5-2494.

If HCR_EL2.{NV, NV1, NV2} are {1, 0, 0}, any exception taken from EL1, and taken to EL1, causes the SPSR_EL1.M[3:2] to be set to 0b10, and not 0b01.

If HCR_EL2.{NV, NV1, NV2} are {1, 1, 0}, then:

- The EL1 translation table Block and Page descriptors:
  - Bit[54] holds the PXN instead of the UXN.
  - Bit[53] is res0.
  - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as follows:
  - Bit[61] is treated as 0 regardless of the actual value.
  - Bit[60] holds the PXNTable instead of the UXNTable.
  - Bit[59] is res0.
- When executing at EL1, the PSTATE.PAN bit is treated as zero for all purposes except reading the value of the bit.
- When executing at EL1, the LDTR* instructions are treated as the equivalent LDR* instructions, and the STTR* instructions are treated as the equivalent STR* instructions.

If HCR_EL2.{NV, NV1, NV2} are {0, 1, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 for all purposes other than reading back the value of the HCR_EL2.NV bit.
- Behaving as if HCR_EL2.NV is 0 and HCR_EL2.NV1 is 0 for all purposes other than reading back the value of the HCR_EL2.NV1 bit.
- Behaving with regard to the HCR_EL2.NV and HCR_EL2.NV1 bits behavior as defined in the rest of this description.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

When ARMv8.3-NV is implemented:

Nested Virtualization. EL1 accesses to certain registers are trapped to EL2, when EL2 is enabled in the current Security state.

0b0 This control does not cause any instructions to be trapped.
0b1 EL1 accesses to VBAR_EL1, ELR_EL1, SPSR_EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

If HCR_EL2.NV is 1 and HCR_EL2.NV1 is 0 then the following effects also apply:

- Any exception taken from EL1, and taken to EL1, causes the SPSR_EL1.M[3:2] to be set to 0b10, and not 0b01.

If the bits HCR_EL2.NV and HCR_EL2.NV1 are both set to 1 then following effects also apply:

- The EL1 translation table Block and Page descriptors:
  - Bit[54] holds the PXN instead of the UXN.
  - Bit[53] is res0.
  - Bit[6] is treated as 0 regardless of the actual value.
• If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as
follows:
  — Bit[61] is treated as 0 regardless of the actual value.
  — Bit[60] holds the PXNTable instead of the UXNTable.
  — Bit[59] is RES0.
• When executing at EL1, the PSTATE.PAN bit is treated as zero for all purposes except
  reading the value of the bit.
• When executing at EL1, the LDTR* instructions are treated as the equivalent LDR*
  instructions, and the STTR* instructions are treated as the equivalent STR* instructions.

If HCR_EL2.NV is 0 and HCR_EL2.NV1 is 1 then the behavior is a CONSTRAINED UNPREDICTABLE
choice of:
• Behaving as if HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 for all purposes other than
  reading than reading back the value of the HCR_EL2.NV bit.
• Behaving as if HCR_EL2.NV is 0 and HCR_EL2.NV1 is 0 for all purposes other than
  reading than reading back the value of the HCR_EL2.NV1 bit.
• Behaving with regard to the HCR_EL2.NV and HCR_EL2.NV1 bits behavior as defined in
  the rest of this description.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

NV, bit [42]

When ARMv8.4-NV is implemented:

Nested Virtualization.

When HCR_EL2.NV2 is 1, redefines register access so that:
  • Instructions accessing the Special purpose registers SPSR_EL2 and ELR_EL2 instead access
    SPSR_EL1 and ELR_EL1 respectively.
  • Instructions accessing the System registers ESR_EL2 and FAR_EL2 instead access
    ESR_EL1 and FAR_EL1.

When HCR_EL2.NV2 is 0, or if ARMv8.4-NV is not implemented, traps functionality that is
permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the
current Security state. This applies to the following operations:
  • EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
  • EL1 accesses to System registers that are not UNDEFINED at EL2.
  • Execution of EL1 or EL2 translation regime address translation and TLB maintenance
    instructions for EL2 and above.

0b0  When this bit is set to 0, HCR_EL2.NV2 == 0 for all purposes other than reading this
register. This control does not cause any instructions to be trapped.

When HCR_EL2.NV2 is 1, no ARMv8.4-NV functionality is implemented.

0b1  When HCR_EL2.NV2 is 0, or if ARMv8.4-NV is not implemented, EL1 accesses to the
specified registers or the execution of the specified instructions are trapped to EL2,
when EL2 is enabled in the current Security state. EL1 read accesses to the CurrentEL
register return a value of 0x2.

When HCR_EL2.NV2 is 1, this control redefines EL1 register accesses so that
instructions accessing SPSR_EL2, ELR_EL2, ESR_EL2, and FAR_EL2 instead access
SPSR_EL1, ELR_EL1, ESR_EL1, and FAR_EL1 respectively.

When HCR_EL2.NV2 is 0, or if ARMv8.4-NV is not implemented, then:
  • The System or Special-purpose registers for which accesses are trapped are as follows:
    — Registers accessed using MRS or MSR with a name ending in _EL2.
— Registers accessed using MRS or MSR with a name ending in _EL12.
— Registers accessed using MRS or MSR with a name ending in _EL02.
— Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und and SPSR_fiq, accessed using MRS or MSR.
— Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.

• The instructions for which the execution is trapped are as follows:
  — EL2 translation regime Address Translation instructions and TLB maintenance instructions.
  — EL1 translation regime Address Translation instructions and TLB maintenance instructions that are only accessible from EL2 and EL3.
  — SMC in an implementation that does not include EL3 and when HCR_EL2.TSC is 1. HCR_EL2.TSC bit is not RES0 in this case.
  — The ERET, ERETTAA, and ERETAB instructions.

--- Note ---

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETTAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

This field resets to an architecturally UNKNOWN value.

When ARMv8.3-NV is implemented:

Nested Virtualization. Traps functionality that is permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the current Security state. This applies to the following operations:

• EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
• EL1 accesses to System registers that are not UNDEFINED at EL2.
• Execution of EL1 or EL2 translation regime address translation and TLB maintenance instructions for EL2 and above.

The possible values are:

0b0  This control does not cause any instructions to be trapped.
0b1  EL1 accesses to the specified registers or the execution of the specified instructions are trapped to EL2, when EL2 is enabled in the current Security state. EL1 read accesses to the CurrentEL register return a value of 0x2.

The System or Special-purpose registers for which accesses are trapped are as follows:

• Registers accessed using MRS or MSR with a name ending in _EL2.
• Registers accessed using MRS or MSR with a name ending in _EL12.
• Registers accessed using MRS or MSR with a name ending in _EL02.
• Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und and SPSR_fiq, accessed using MRS or MSR.
• Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.

The instructions for which the execution is trapped are as follows:

• EL2 translation regime Address Translation instructions and TLB maintenance instructions.
• EL1 translation regime Address Translation instructions and TLB maintenance instructions that are only accessible from EL2 and EL3.
• The ERET, ERETTAA, and ERETAB instructions.
### Note

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

- SMC in an implementation that does not include EL3 and when HCR_EL2.TSC is 1. HCR_EL2.TSC bit is not RES0 in this case.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally **UNKNOWN** value.

---

**Otherwise:**

Reserved, RES0.

### API, bit [41]

**When ARMv8.3-PAuth is implemented:**

Controls the use of instructions related to Pointer Authentication:

- PACGA, XPCAD, XPCAI, and XPACLRI.
- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZ, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETEAA, ERETEB, LDRAA, LDRAB when:
  - In EL0, when HCR_EL2.TGE==0 or HCR_EL2.E2H==0, and the associated SCTLR_EL1.En<N><M>=1.
  - In EL1, the associated SCTLR_EL1.En<N><M>=1.

0b0 The instructions related to Pointer Authentication are trapped to EL2, when EL2 is enabled in the current Security state and the instructions are enabled for the EL1&0 translation regime, from:

- EL0 when HCR_EL2.TGE==0 or HCR_EL2.E2H==0.
- EL1.

If HCR_EL2.NV is 1, the HCR_EL2.NV trap takes precedence over the HCR_EL2.API trap for the ERETEAA and ERETEB instructions.

0b1 This control does not cause any instructions to be trapped.

---

**Note**

If ARMv8.3-PAuth is implemented but EL2 is not implemented or disabled in the current Security state, the system behaves as if this bit is 1.

This field resets to an architecturally **UNKNOWN** value.

---

**Otherwise:**

Reserved, RES0.

### APK, bit [40]

**When ARMv8.3-PAuth is implemented:**

Trap registers holding "key" values for Pointer Authentication. Traps accesses to the following registers from EL1 to EL2, when EL2 is enabled in the current Security state:

- APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1, APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APGAKeyLo_EL1, and APGAKeyHi_EL1.

0b0 Access to the registers holding "key" values for pointer authentication from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

0b1 This control does not cause any instructions to be trapped.
Note

If ARMv8.3-PAuth is implemented but EL2 is not implemented or is disabled in the current Security state, the system behaves as if this bit is 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [39]
Reserved, RES0.

MIOCNCE, bit [38]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the EL1&0 translation regimes.

0b0 For the EL1&0 translation regimes, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

0b1 For the EL1&0 translation regimes, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see Mismatched memory attributes on page B2-132.

This field can be implemented as RAZ/WI.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

TEA, bit [37]
Route synchronous External abort exceptions to EL2. If the RAS Extension is implemented, the possible values of this bit are:

0b0 This control does not cause exceptions to be routed from EL0 and EL1 to EL2.

0b1 Route synchronous External abort exceptions from EL0 and EL1 to EL2, when EL2 is enabled in the current Security state, if not routed to EL3.

When the RAS Extension is not implemented, this field is RES0.

This field resets to an architecturally UNKNOWN value.

TERR, bit [36]

When RAS is implemented:
Trap Error record accesses. Trap accesses to the following registers from EL1 to EL2:

EL1 using AArch64: ERRIDR_EL1, ERRSELR_EL1, ERXADDR_EL1, ERXCTRL_EL1, ERXFER_EL1, ERXMISC0_EL1, ERXMISC1_EL1, and ERXSTATUS_EL1. When ARMv8.4-RAS is implemented, ERXMISC2_EL1, and ERXMISC3_EL1.

EL1 using AArch32: ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTRL, ERXCTRL2, ERXFER, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS. When ARMv8.4-RAS is implemented, ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

0b0 This control does not cause any instructions to be trapped.

0b1 Accesses to the specified registers from EL1 generate a Trap exception to EL2, when EL2 is enabled in the current Security state.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
**TLOR, bit [35]**

*From ARMv8.1:*

Trap LOR registers. Traps accesses to the LORSA_EL1, LOREA_EL1, LORN_EL1, LORC_EL1, and LORID_EL1 registers from EL1 to EL2, when EL2 is enabled in the current Security state.

- **0b0**: This control does not cause any instructions to be trapped.
- **0b1**: EL1 accesses to the LOR registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**E2H, bit [34]**

*From ARMv8.1:*

EL2 Host. Enables a configuration where a Host Operating System is running in EL2, and the Host Operating System's applications are running in EL0.

- **0b0**: The facilities to support a Host Operating System at EL2 are disabled.
- **0b1**: The facilities to support a Host Operating System at EL2 are enabled.

For information on the behavior of this bit see *Behavior of HCR_EL2.E2H on page D5-2486.*

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**ID, bit [33]**

Stage 2 Instruction access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

- **0b0**: This control has no effect on stage 2 of the EL1&0 translation regime.
- **0b1**: Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

**CD, bit [32]**

Stage 2 Data access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

- **0b0**: This control has no effect on stage 2 of the EL1&0 translation regime for data accesses and translation table walks.
- **0b1**: Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.
**RW, bit [31]**

Execution state control for lower Exception levels:

0b0  Lower levels are all AArch32.

0b1  The Execution state for EL1 is AArch64. The Execution state for EL0 is determined by the current value of PSTATE.nRW when executing at EL0.

If all lower Exception levels cannot use AArch32 then this bit is RAO/WI.

In an implementation that includes EL3, when EL2 is not enabled in Secure state, the PE behaves as if this bit has the same value as the SCR_EL3.RW bit for all purposes other than a direct read or write access of HCR_EL2.

The RW bit is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as if for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

**TRVM, bit [30]**

Trap Reads of Virtual Memory controls. Traps EL1 reads of the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, from both Execution states. The registers for which read accesses are trapped are as follows:

EL1 using AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.

EL1 using AArch32: SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AFISR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0b0  This control does not cause any instructions to be trapped.

0b1  EL1 read accesses to the specified Virtual Memory controls are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

**HCD, bit [29]**

HVC instruction disable. Disables EL1 execution of HVC instructions, from both Execution states, when EL2 is enabled in the current Security state.

0b0  HVC instruction execution is enabled at EL2 and EL1.

0b1  HVC instructions are UNDEFINED at EL2 and EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed.

--- **Note** ---

HVC instructions are always UNDEFINED at EL0.

---

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

**TDZ, bit [28]**

Trap DC ZVA instructions. Traps EL0 and EL1 execution of DC ZVA instructions to EL2, when EL2 is enabled in the current Security state, from AArch64 state only.

0b0  This control does not cause any instructions to be trapped.

0b1  In AArch64 state, any attempt to execute an instruction this trap applies to at EL1, or at EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2 when EL2 is enabled in the current Security state.
Reading the DCZID_EL0 returns a value that indicates that the instructions this trap applies to are not supported.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

**TGE, bit [27]**

Trap General Exceptions, from EL0.

<table>
<thead>

</thead>
<tbody>
<tr>
<td>0b0</td>
<td>This control has no effect on execution at EL0.</td>
</tr>
</tbody>
</table>
| 0b1     | When EL2 is not enabled in the current Security state, this control has no effect on execution at EL0. When EL2 is enabled in the current Security state, in all cases:  
  - All exceptions that would be routed to EL1 are routed to EL2.  
  - The SCTLR_EL1.M field, or the SCTLR.M field if EL1 is using AArch32, is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1 or SCTLR.  
  - All virtual interrupts are disabled.  
  - Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.  
  - An exception return to EL1 is treated as an illegal exception return. When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0, additionally:  
    - The HCR_EL2.{FMO, IMO, AMO} fields are treated as being 1 for all purposes other than a direct read or write access of HCR_EL2.  
    - The MDCR_EL2.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of MDCR_EL2.  
  For information on the behavior of this bit when E2H is 1, see Behavior of HCR_EL2.E2H on page D5-2486. |

HCR_EL2.TGE must not be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

**TVM, bit [26]**

Trap Virtual Memory controls. Traps EL1 writes to the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, from both Execution states. The registers for which write accesses are trapped are as follows:

- EL1 using AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.
- EL1 using AArch32: SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

</table>

This field resets to an architecturally UNKNOWN value.
TTLB, bit [25]

*When ARMv8.4-TLBI is implemented:*

Trap TLB maintenance instructions. Traps EL1 execution of TLB maintenance instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states. This applies to the following instructions:

- When EL1 is using AArch64, TLBI VMALLEI1IS, TLBI VAEEI1IS, TLBI ASIDEI1IS, TLBI VAEEI1IS, TLBI VAALEI1IS, TLBI VMALLEI1, TLBI VAEEI1, TLBI ASIDEI1, TLBI VAEEI1, TLBI VAALLEI1, TLBI VMALLEI1OS, TLBI VAEEI1OS, TLBI ASIDEI1OS, TLBI VAEEI1OS, TLBI VAALLEI1OS, TLBI RVAEI1, TLBI RVAAEI1OS, TLBI RVVAEI1, TLBI RVRAEI1, TLBI RVAAEI1OS, TLBI RVRAEI1OS.

- When EL1 is using AArch32, TLBIALLIS, TLMVVAIS, TLMVASIS, TLMVAAIS, TLMVAALIS, TLMVAALS, ITLBIALL, ITLBMVA, ITLBIASID, DTLBIALL, DTLBMVA, DTLBISID, TLMVALL, TLMVA, TLMVASID, TLMVAA, TLMVAL, TLMVAAL.

0b0  This control does not cause any instructions to be trapped.

0b1  EL1 execution of the specified TLB maintenance instructions are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

*From ARMv8.0:*

Trap TLB maintenance instructions. Traps EL1 execution of TLB maintenance instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states. This applies to the following instructions:

- When EL1 is using AArch64, TLBI VMALLEI1IS, TLBI VAEEI1IS, TLBI ASIDEI1IS, TLBI VAEEI1IS, TLBI VAALEI1IS, TLBI VMALLEI1, TLBI VAEEI1, TLBI ASIDEI1, TLBI VAEEI1, TLBI VAALLEI1.

- When EL1 is using AArch32, TLBIALLIS, TLMVVAIS, TLMVASIS, TLMVAAIS, TLMVAALIS, TLMVAALS, ITLBIALL, ITLBMVA, ITLBIASID, DTLBIALL, DTLBMVA, DTLBISID, TLMVALL, TLMVA, TLMVASID, TLMVAA, TLMVAL, TLMVAAL.

0b0  This control does not cause any instructions to be trapped.

0b1  EL1 execution of the specified TLB maintenance instructions are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL1 or EL0 using AArch64, and at EL1 using AArch32, to EL2 when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL0 is using AArch64, IC IV AU, DC CV AU. However, if the value of SCTLR_EL1.UCl is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

- When EL1 is using AArch64, IC IV AU, IC IALLU, IC IALLUIS, DC CV AU.

- When EL1 is using AArch32, ICIMVVAU, ICIALLU, ICIALLUIUS, DCCMVVAU.
-- Note --
An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- IC IAILUIS and IC IAILU are always UNDEFINED at EL0 using AArch64.
- ICIMVAU, ICIALLU, ICIALLUI, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

0b0  This control does not cause any instructions to be trapped.
0b1  Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

TPCP, bit [23]

When ARMv8.2-DCPoP is implemented:

Trap data or unified cache maintenance instructions that operate to the Point of Coherency or Persistence. Traps execution of those cache maintenance instructions at EL1 or EL0 using AArch64, and at EL1 using AArch32, to EL2 when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL0 is using AArch64, DC CIVAC, DC CVAC, DC CVAP. However, if the value of SCTLR_EL1.UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.
- When EL1 is using AArch64, DC IVAC, DC CIVAC, DC CVAC, DC CVAP.
- When EL1 is using AArch32, DCIMVAC, DCCIMVAC, DCCMVAC.

-- Note --

- An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:
  - AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.
  - DCIMVAC, DCCIMVAC, and DCCMVAC are always UNDEFINED at EL0 using AArch32.
- In ARMv8.0 this field is named TPC. From ARMv8.2 it is named TPCP.

0b0  This control does not cause any instructions to be trapped.
0b1  Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If HCR_EL2.{E2H, TGE} is set to {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.
Otherwise:

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps execution of those cache maintenance instructions at EL1 or EL0 using AArch64, and at EL1 using AArch32, to EL2 when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL0 is using AArch64, DC CIV AC, DC CV AC. However, if the value of SCTLR_EL1.UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.
- When EL1 is using AArch64, DC IV AC, DC CIV AC, DC CV AC.
- When EL1 is using AArch32, DCIMVAC, DCCIMVAC, DCCMVAC.

Note

- An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:
  - AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.
  - DCIMVAC, DCCIMVAC, and DCCMVAC are always UNDEFINED at EL0 using AArch32.
- In ARMv8.0 this field is named TPC. From ARMv8.2 it is named TPCP.

0b0
This control does not cause any instructions to be trapped.

0b1
Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at EL1 using AArch64, and at EL1 using AArch32, to EL2 when EL2 is enabled in the current Security state. This applies to the following instructions:

- When EL1 is using AArch64, DC ISW, DC CSW, DC CISW.
- When EL1 is using AArch32, DCISW, DCCSW, DCCISW.

Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0
This control does not cause any instructions to be trapped.

0b1
Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps EL1 accesses to the Auxiliary Control Registers to EL2, when EL2 is enabled in the current Security state, from both Execution states. This applies to the following register accesses:

- EL1 using AArch64: ACTLR_EL1.
• EL1 using AArch32: ACTLR and, if implemented, ACTLR2.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to the specified registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2, when EL2 is enabled in the current Security state. This applies to the following register accesses:

AArch64: The following reserved encoding spaces:

• IMPLEMENTATION DEFINED System instructions, which are accessed using SYS and SYSL, with CRn == \{11, 15\}.

• IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the S3_<op1>_<Cn>_<Cm>_<op2> register name.

AArch32: MCR and MRC instructions accessing the following encodings:

• All coproc==p15, CRn==c9, opc1 == \{0-7\}, CRm == \{c0-c2, c5-c8\}, opc2 == \{0-7\}.

• All coproc==p15, CRn==c10, opc1 ==\{0-7\}, CRm == \{c0, c1, c4, c8\}, opc2 == \{0-7\}.

• All coproc==p15, CRn==c11, opc1==\{0-7\}, CRm == \{c0-c8, c15\}, opc2 == \{0-7\}.

When the value of HCR_EL2.TIDCP is 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2. If it is not, then it is UNDEFINED, and any attempt to access it from EL0 generates an exception that is taken to EL1.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2, when EL2 is enabled in the current Security state.

This field resets to an architecturally UNKNOWN value.

TSC, bit [19]

Trap SMC instructions. Traps EL1 execution of SMC instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states.

0b0 This control does not cause any instructions to be trapped.

0b1 If EL3 is implemented, then any attempt to execute an SMC instruction at EL1 using AArch64 or EL1 using AArch32 is trapped to EL2, when EL2 is enabled in the current Security state, regardless of the value of SCR_EL3.SMD.

If EL3 is not implemented, ARMv8.3-NV is implemented, and HCR_EL2.NV is 1, then any attempt to execute an SMC instruction at EL1 using AArch64 is trapped to EL2, when EL2 is enabled in the current Security state.

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

If EL3 is not implemented, and HCR_EL2.NV is 0, this bit is RES0.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

TID3, bit [18]

Trap ID group 3. Traps EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state:
AArch64: ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFIR1_EL1, ID_MMFIR2_EL1, ID_MMFIR3_EL1, ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, ID_ISAR6_EL1, MVFR0_EL1, MVFR1_EL1, MVFR2_EL1, MVFR3_EL1, ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64MMFR3_EL1, ID_AA64MMFR4_EL1, ID_AA64MMFR5_EL1, ID_AA64AFR0_EL1, ID_AA64AFR1_EL1, ID_AA64AFR2_EL1, ID_AA64AFR3_EL1, ID_AA64AFR4_EL1, ID_AA64AFR5_EL1, ID_MMFIR4_EL1, and ID_MMFR4_EL1, except that if ID_MMFR4_EL1 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4_EL1 are trapped.

It is IMPLEMENTATION DEFINED whether this field traps MRS accesses to encodings in the following range that are not already mentioned in this field description:

- Op0 == 3, op1 == 0, CRn == c0, CRm == {c2-c7}, op2 == {0-7}.

AArch32: ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MFIR0, ID_MFIR1, ID_MFIR2, ID_MFIR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVIR0, MVIR1, MVIR2, and ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4 are trapped.

MRC access to any of the following encodings are also trapped:

- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 read accesses to ID group 2 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

**TID2, bit [17]**

Trap ID group 2. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

AArch64:

- EL1 reads of CTR_EL0, CCSIDR_EL1, CCSIDR2_EL1, CLIDR_EL1, and CSSELR_EL1.
- EL0 reads of CTR_EL0, except that if the value of SCTLR_EL1.UCT is 0 then EL0 reads of CTR_EL0 are UNDEFINED and any resulting exception takes precedence over this trap.
- EL1 writes to CSSELR_EL1.

AArch32:

- EL1 reads of the CTR, CCSIDR, CCSIDR2, CLIDR, and CSSELR.
- EL1 writes to the CSSELR.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified EL1 and EL0 accesses to ID group 2 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.
TID1, bit [16]  
Trap ID group 1. Traps EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state:

AArch64: REVIDR_EL1, AIDR_EL1.
AArch32: TCMTR, TLBTR, REVIDR, AIDR.

0b0  This control does not cause any instructions to be trapped.
0b1  The specified EL1 read accesses to ID group 1 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

TID0, bit [15]  
Trap ID group 0. Traps the following register accesses to EL2:
AArch64: None.
AArch32:
  • EL1 reads of the JIDR.
  • If the JIDR is RAZ from EL0, EL0 reads of the JIDR.
  • EL1 reads of the FPSID.

--- Note ---
  • It is IMPLEMENTATION DEFINED whether the JIDR is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then any resulting exception takes precedence over this trap.
  • The FPSID is not accessible at EL0 using AArch32.
  • Writes to the FPSID are ignored, and not trapped by this control.

0b0  This control does not cause any instructions to be trapped.
0b1  The specified EL1 read accesses to ID group 0 registers are trapped to EL2, when EL2 is enabled in the current Security state.

In an AArch64 only implementation, this bit is res0.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

TWE, bit [14]  
Traps EL0 and EL1 execution of WFE instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states.

0b0  This control does not cause any instructions to be trapped.
0b1  Any attempt to execute a WFE instruction at EL0 or EL1 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE or SCTLR_EL1.nTWE.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.
When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

**TWI, bit [13]**

Traps EL0 and EL1 execution of WFI instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states.

- **0b0**  This control does not cause any instructions to be trapped.
- **0b1**  Any attempt to execute a WFI instruction at EL0 or EL1 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI or SCTLR_EL1.nTWI.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- **Note** ---

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

**DC, bit [12]**

Default Cacheability.

- **0b0**  This control has no effect on the EL1&0 translation regime.
- **0b1**  In both Security states:
  - When EL1 is using AArch64, the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1.
  - When EL1 is using AArch32, the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of SCTLR.
  - The PE behaves as if the value of the HCR_EL2.VM field is 1 for all purposes other than returning the value of a direct read of HCR_EL2.
  - The memory type produced by stage 1 of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2, EL2&0, and EL3 translation regimes.

This field is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this field behaves as 0 for all purposes other than a direct read of the value of this field.

This field resets to an architecturally UNKNOWN value.

**BSU, bits [11:10]**

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from EL1 or EL0:

- **0b00**  No effect.
- **0b01**  Inner Shareable.
- **0b10**  Outer Shareable.
- **0b11**  Full system.
This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When ARMv8.1-VHE is implemented, and the value of \texttt{HCR\_EL2.\{E2H, TGE\}} is \{1, 1\}, this field behaves as \texttt{0b0} for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally \texttt{UNKNOWN} value.

**FB, bit [9]**

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from EL1:

- AArch32: \texttt{BPIALL, TLBIA, TLBIMV, TLBIASID, DTLBIAL, DTLBIV, DTLBIASID, ITLBIAL, ITLBMV, ITLBIASID, TLBIMVAA, ICIALL, TLBIMVA, ITLBMVA.}
- AArch64: \texttt{TLBIMVALE1, TLBI VA, TLBI ASIDE, TLB I V A, TLBI VALE, TLBI VAALE, IC I ALLU, TLBI RV A, TLBI RVAE, TLBI RVALE, TLBI RVAALE.}

\texttt{0b0} This field has no effect on the operation of the specified instructions.

\texttt{0b1} When one of the specified instruction is executed at EL1, the instruction is broadcast within the Inner Shareable shareability domain.

When \texttt{HCR\_EL2.TGE} is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally \texttt{UNKNOWN} value.

**VSE, bit [8]**

Virtual SError interrupt.

\texttt{0b0} This mechanism is not making a virtual SError interrupt pending.

\texttt{0b1} A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is only enabled when the value of \texttt{HCR\_EL2.\{TGE, AMO\}} is \{0, 1\}.

This field resets to an architecturally \texttt{UNKNOWN} value.

**VI, bit [7]**

Virtual IRQ Interrupt.

\texttt{0b0} This mechanism is not making a virtual IRQ pending.

\texttt{0b1} A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of \texttt{HCR\_EL2.\{TGE, IMO\}} is \{0, 1\}.

This field resets to an architecturally \texttt{UNKNOWN} value.

**VF, bit [6]**

Virtual FIQ Interrupt.

\texttt{0b0} This mechanism is not making a virtual FIQ pending.

\texttt{0b1} A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of \texttt{HCR\_EL2.\{TGE, FMO\}} is \{0, 1\}.

This field resets to an architecturally \texttt{UNKNOWN} value.

**AMO, bit [5]**

Physical SError interrupt routing.

\texttt{0b0} When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:

- Physical SError interrupts are not taken to EL2.
- When the value of \texttt{HCR\_EL2.TGE} is 0, if the PE is executing at EL2 using AArch64, physical SError interrupts are not taken unless they are routed to EL3 by the \texttt{SCR\_EL3.EA} bit.
- Virtual SError interrupts are disabled.
0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
   • Physical SError interrupts are taken to EL2, unless they are routed to EL3.
   • When the value of HCR_EL2.TGE is 0, then virtual SError interrupts are enabled.

If EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1:
   • Regardless of the value of the AMO bit physical asynchronous External aborts and SError interrupts target EL2 unless they are routed to EL3.
   • When ARMv8.1-VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
   • When ARMv8.1-VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see Asynchronous exception routing on page D1-2199.

This field resets to an architecturally UNKNOWN value.

IMO, bit [4]
Physical IRQ Routing.
0b0 When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:
   • Physical IRQ interrupts are not taken to EL2.
   • When the value of HCR_EL2.TGE is 0, if the PE is executing at EL2 using AArch64, physical IRQ interrupts are not taken unless they are routed to EL3 by the SCR_EL3.IRQ bit.
   • Virtual IRQ interrupts are disabled.
0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
   • Physical IRQ interrupts are taken to EL2, unless they are routed to EL3.
   • When the value of HCR_EL2.TGE is 0, then Virtual IRQ interrupts are enabled.

If EL2 is enabled in the current Security state, and the value of HCR_EL2.TGE is 1:
   • Regardless of the value of the IMO bit, physical IRQ Interrupts target EL2 unless they are routed to EL3.
   • When ARMv8.1-VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
   • When ARMv8.1-VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see Asynchronous exception routing on page D1-2199.

This field resets to an architecturally UNKNOWN value.

FMO, bit [3]
Physical FIQ Routing.
0b0 When executing at Exception levels below EL2, and EL2 is enabled in the current Security state:
   • Physical FIQ interrupts are not taken to EL2.
   • When the value of HCR_EL2.TGE is 0, if the PE is executing at EL2 using AArch64, physical FIQ interrupts are not taken unless they are routed to EL3 by the SCR_EL3.FIQ bit.
   • Virtual FIQ interrupts are disabled.
0b1 When executing at any Exception level, and EL2 is enabled in the current Security state:
   • Physical FIQ interrupts are taken to EL2, unless they are routed to EL3.
   • When HCR_EL2.TGE is 0, then Virtual FIQ interrupts are enabled.
If EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1:

- Regardless of the value of the FMO bit, physical FIQ Interrupts target EL2 unless they are routed to EL3.
- When ARMv8.1-VHE is not implemented, or if HCR_EL2.E2H is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When ARMv8.1-VHE is implemented and HCR_EL2.E2H is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see Asynchronous exception routing on page D1-2199.

This field resets to an architecturally UNKNOWN value.

PTW, bit [2]

Protected Table Walk. In the EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs, then the value of this bit determines the behavior:

0b0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
0b1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

SWIO, bit [1]

Set/Way Invalidation Override. Causes EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

0b0 This control has no effect on the operation of data cache invalidate by set/way instructions.
0b1 Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: DCISW performs the same invalidation as a DCCISW instruction.
AArch64: DCISW performs the same invalidation as a DCCISW instruction.

This bit can be implemented as RES1.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

This field resets to an architecturally UNKNOWN value.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the EL1&0 translation regime, when EL2 is enabled in the current Security state.

0b0 EL1&0 stage 2 address translation disabled.
0b1 EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

This bit is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.
Accessing the HCR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2</td>
<td>11</td>
<td>0001</td>
<td>100</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.45   HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

Configurations

AArch64 System register HPFAR_EL2[31:0] is architecturally mapped to AArch32 System register HPFAR[31:0].
If EL2 is not implemented, this register is RES0 from EL3.
This register has no effect if EL2 is not enabled in the current Security state.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

The HPFAR_EL2 bit assignments are:

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

NS, bit [63]

From ARMv8.4:
Faulting IPA address space.
0b0   Faulting IPA is from the Secure IPA space.
0b1   Faulting IPA is from the Non-secure IPA space.
For data or instruction aborts taken to Non-secure EL2, this field is RES0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [62:44]

Reserved, RES0.

FIPA[51:48], bits [43:40]

From ARMv8.2, or if ARMv8.2-LPA is implemented:
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

FIPA[47:12], bits [39:4]

Bits [47:12] of the faulting intermediate physical address.
For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use for the stage 1 translation, the FIPA[51:48] bits form the upper part of the address value. For implementations or stage 1 translation granules with fewer than 52 physical address bits the FIPA[51:48] bits are RES0.

The HPFAR_EL2 is written for:

- Translation or Access faults in the second stage of translation.
- An abort in the second stage of translation performed during the translation table walk of a first stage translation, caused by a Translation fault, an Access flag fault, or a Permission fault.
- A stage 2 Address size fault.

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

For all other exceptions taken to EL2, this register is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPFAR_EL2</td>
<td>11</td>
<td>0110</td>
<td>100</td>
<td>100</td>
<td>000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

---

If \((\text{SCR\_EL3\_NS} == 1 \text{ or } \text{SCR\_EL3\_EEL2} == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& \text{HCR\_EL2\_E2H} == 0 \&\& \text{HCR\_EL2\_NV} == 1\), then accesses at EL1 are trapped to EL2.

---

If \((\text{SCR\_EL3\_NS} == 1 \text{ or } \text{SCR\_EL3\_EEL2} == 1) \&\& \text{IsUsingAArch64(EL2)} \&\& \text{HCR\_EL2\_E2H} == 1 \&\& \text{HCR\_EL2\_TGE} == 0 \&\& \text{HCR\_EL2\_NV} == 1\), then accesses at EL1 are trapped to EL2.
### HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

**Purpose**

Controls trapping to EL2 of EL1 or lower AArch32 accesses to the System register in the coproc == 0b1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

**Configurations**

AArch64 System register HSTR_EL2[31:0] is architecturally mapped to AArch32 System register HSTR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

If no Exception level can use AArch32, then this register is RES0.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSTR_EL2 is a 64-bit register.

**Field descriptions**

The HSTR_EL2 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Fields T14 and T4 are RES0.

The remaining fields control whether EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 0b1111 encoding space are trapped to EL2:

- **0b0** This control has no effect on EL0 or EL1 accesses to System registers.
- **0b1** Any EL1 MCR or MRC access with coproc == 0b1111 and CRn == <n> is trapped to EL2. An EL0 MCR or MRC access with these values is trapped to EL2 only if the access is not UNDEFINED when the value of this field is 0. Any EL1 MCRR or MRRC access with coproc == 0b1111 and CRm == <n> is trapped to EL2. An EL0 MCRR or MRRC access with these values is trapped to EL2 only if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR_EL2.T7 is 1, for instructions executed at EL1:

- An MCR or MRC instruction with coproc set to 0b1111 and <CRn> set to c7 is trapped to EL2.
An MCRR or MRRC instruction with coproc set to 0b1111 and <CRm> set to c7 is trapped to EL2.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

This field resets to an architecturally UNKNOWN value.

Accessing the HSTR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>HSTR_EL2</td>
<td>11</td>
<td>0001</td>
<td>100</td>
<td>011</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: - EL1: - EL2: n/a EL3: RW</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.47  ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0

The ID_AA64AFR0_EL1 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch64 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64AFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64AFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0</td>
</tr>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.48   ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1

The ID_AA64AFR1_EL1 characteristics are:

**Purpose**

Reserved for future expansion of information about the IMPLEMENTATION DEFINED features of the
PE in AArch64 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme
for fields in ID registers* on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64AFR1_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64AFR1_EL1 bit assignments are:

```
63  0
  ??  ??  RES0 ??
```

Bits [63:0]

Reserved, RES0.

**Accessing the ID-AA64AFR1_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>SCR_EL3.EEL2 == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>SCR_EL3.EEL2 == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If \((\text{SCR\_EL3.NS} = 1 \lor \text{SCR\_EL3.EEL2} = 1) \land \text{IsUsingAArch64(EL2)} \land \text{HCR\_EL2.TID3} = 1\), then read accesses at EL1 are trapped to EL2.
D12.2.49 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch64 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

The external register EDDFR gives information from this register.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64DFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64DFR0_EL1 bit assignments are:

</tbody>
</table>
CTX_CMPs, bits [31:28]
Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

Bits [27:24]
Reserved, RES0.

WRPs, bits [23:20]
Number of watchpoints, minus 1. The value of 0b0000 is reserved.

Bits [19:16]
Reserved, RES0.

BRPs, bits [15:12]
Number of breakpoints, minus 1. The value of 0b0000 is reserved.

PMUVer, bits [11:8]
Performance Monitors Extension version.
This field does not follow the standard ID scheme, but uses the Alternative ID scheme described in Alternative ID scheme used for the Performance Monitors Extension version on page D12-2682.
Defined values are:
0b0000 Performance Monitors Extension not implemented.
0b0001 Performance Monitors Extension implemented, PMUv3.
0b0100 PMUv3 for ARMv8.1. As 0b0001, and also includes support for:
  • Extended 16-bit PMEVTYPE<EL0.evctCount field.
  • If EL2 is implemented, the MDCR_EL2.HPMD control bit.
0b0101 PMUv3 for ARMv8.4. As 0b0100 and also includes support for the PMMIR_EL1 register.
0b1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value in new implementations.
ARMv8.1-PMU implements the functionality added by the value 0b0100.
ARMv8.4-PMU implements the functionality added by the value 0b0101.
All other values are reserved.
From ARMv8.1, the value 0b0001 is not permitted.
From ARMv8.4, the value 0b0100 is not permitted.

TraceVer, bits [7:4]
Trace support. Indicates whether System register interface to a PE trace unit is implemented.
Defined values are:
0b0000 PE trace unit System registers not implemented.
0b0001 PE trace unit System registers implemented.
All other values are reserved.
A value of 0b0000 only indicates that no System register interface to a PE trace unit is implemented. A PE trace unit might nevertheless be implemented without a System register interface.
See the ETM Architecture Specification for more information.

DebugVer, bits [3:0]
Debug architecture version. Indicates presence of ARMv8 debug architecture. Defined values are:
0b0110 ARMv8 debug architecture.
0b0111 ARMv8 debug architecture with Virtualization Host Extensions.
0b1000  ARMv8.2 debug architecture
0b1001  ARMv8.4 debug architecture

All other values are reserved.

ARMv8.2-Debug adds the functionality indicated by the value 0b1000.

• If ARMv8.1-VHE is not implemented the only permitted value is 0b0110.
• In an ARMv8.0 implementation the value 0b1000 is not permitted.

### Accessing the ID_AA64DFR0_EL1

This register can be read using MRS with the following syntax:

\[ \text{MRS } <Xt>, <systemreg> \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64DFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0101</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.50  ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

**Purpose**

Reserved for future expansion of top level information about the debug system in AArch64 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64DFR1_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64DFR1_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit Assignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:0]</td>
</tr>
<tr>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
```

**Accessing the ID_AA64DFR1_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64DFR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>001</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RO, EL1: n/a, EL2: RO, EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see "Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191." Subject to the prioritization rules:

If $(\text{SCR\_EL3.NS} == 1 || \text{SCR\_EL3.EEL2} == 1) && \text{IsUsingAArch64(EL2)} && \text{HCR\_EL2.TID3} == 1$, then read accesses at EL1 are trapped to EL2.
D12.2.51 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

**Purpose**

Provides information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64ISAR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64ISAR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

**Bits [63:60]**

Reserved, RES0.

**TLB, bits [59:56]**

*From ARMv8.4:*

Indicates support for Outer shareable and TLB range maintenance instructions. Defined values are:

- 00000: Outer shareable and TLB range maintenance instructions are not implemented.
- 00001: Outer shareable TLB maintenance instructions are implemented.
- 00010: Outer shareable and TLB range maintenance instructions are implemented.

All other values are reserved.

ARMv8.4-TLBI implements the functionality identified by the values 00001 and 00010.

From ARMv8.4, the only permitted value is 00010.

**Otherwise:**

Reserved, RES0.

**TS, bits [55:52]**

Indicates support for flag manipulation instructions. Defined values are:

- 00000: No flag manipulation instructions are implemented.
- 00001: CFINV, RMIF, SETF16, and SETF8 instructions are implemented.

All other values are reserved.

ARMv8.4-CondM implements the functionality identified by the value 00001.

From ARMv8.4, the only permitted value is 00001.
FHM, bits [51:48]

From ARMv8.2:
Indicates whether FMLAL and FMLSL instructions are implemented.
0b0000  FMLAL and FMLSL instructions are not implemented.
0b0001  FMLAL and FMLSL instructions are implemented.
All other values are reserved.
ARMv8.2-FHM implements the functionality identified by the value 0b0001.
From ARMv8.2, the permitted values are 0b0000 and 0b0001.

Otherwise:
Reserved, RES0.

DP, bits [47:44]

From ARMv8.2:
Dot Product instructions implemented in AArch64 state. Defined values are:
0b0000  No Dot Product instructions implemented.
0b0001  UDOT and SDOT instructions implemented.
All other values are reserved.
ARMv8.2-DotProd implements the functionality identified by the value 0b0001.
From ARMv8.2, the permitted values are 0b0000 and 0b0001.

Otherwise:
Reserved, RES0.

SM4, bits [43:40]

From ARMv8.2:
SM4 instructions implemented in AArch64 state. Defined values are:
0b0000  No SM4 instructions implemented.
0b0001  SM4E and SM4EKEY instructions implemented.
All other values are reserved.
If ARMv8.2-SM is not implemented the value 0b0001 is reserved.
From ARMv8.2, the permitted values are 0b0000 and 0b0001.
This field must have the same value as ID_AA64ISAR0_EL1.SM3.

Otherwise:
Reserved, RES0.

SM3, bits [39:36]

From ARMv8.2:
SM3 instructions implemented in AArch64 state. Defined values are:
0b0000  No SM3 instructions implemented.
0b0001  SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, and SM3PARTW2 instructions implemented.
All other values are reserved.
If ARMv8.2-SM is not implemented the value 0b0001 is reserved.
ARMv8.2-SM implements the functionality identified by the value 0b0001.
From ARMv8.2, the permitted values are 0b0000 and 0b0001.
This field must have the same value as ID_AA64ISAR0_EL1.SM4.
SHA3, bits [35:32]

From ARMv8.2:
SHA3 instructions implemented in AArch64 state. Defined values are:
0b0000  No SHA3 instructions implemented.
0b0001  EOR3, RAX1, XAR, and BCAX instructions implemented. All other values are reserved.
If ARMv8.2-SHA is not implemented the value 0b0001 is reserved. ARMv8.2-SHA implements the functionality identified by the value 0b0001.
From ARMv8.2, the permitted values are 0b0000 and 0b0001.
If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, then this field must have the value 0b0000.
If the value of this field is 0b0001, then ID_AA64ISAR0_EL1.SHA2 must have the value 0b0010.

Otherwise:
Reserved, RES0.

RDM, bits [31:28]

From ARMv8.1:
SQRDMLAH and SQRDMLSH instructions implemented in AArch64 state. Defined values are:
0b0000  No SQRDMLAH and SQRDMLSH instructions implemented.
0b0001  SQRDMLAH and SQRDMLSH instructions implemented. All other values are reserved.
ARMv8.1-RDMA implements the functionality identified by the value 0b0001.
From ARMv8.1, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

Bits [27:24]
Reserved, RES0.

Atomic, bits [23:20]

From ARMv8.1:
Atomic instructions implemented in AArch64 state. Defined values are:
0b0000  No Atomic instructions implemented.
0b0010  LDADD, LDCLR, LDEOR, LDSET, LDSMAX, LDSMIN, LDUMAX, LDUMIN, CAS, CASP, and SWP instructions implemented. All other values are reserved.
implements the functionality identified by the value 0b0010.
From ARMv8.1, the only permitted value is 0b0010.

Otherwise:
Reserved, RES0.

CRC32, bits [19:16]
CRC32 instructions implemented in AArch64 state. Defined values are:
0b0000  No CRC32 instructions implemented.
0b0001  CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX instructions implemented.
All other values are reserved.
In ARMv8.0, the permitted values are 0b0000 and 0b0001.
From ARMv8.1, the only permitted value is 0b0001.

SHA2, bits [15:12]
SHA2 instructions implemented in AArch64 state. Defined values are:
- 0b0000: No SHA2 instructions implemented.
- 0b0001: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.
- 0b0010: As 0b0001, plus SHA512H, SHA512H2, SHA512SU0, and SHA512SU1 instructions implemented.

All other values are reserved.
If ARMv8.2-SHA is not implemented the value 0b0010 is reserved.
From ARMv8.2, the permitted values are 0b0000, 0b0001, and 0b0010.
If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, then this field must have the value 0b0000.
If the value of this field is 0b0010, then ID_AA64ISAR0_EL1.SHA3 must have the value 0b0001.

SHA1, bits [11:8]
SHA1 instructions implemented in AArch64 state. Defined values are:
- 0b0000: No SHA1 instructions implemented.
- 0b0001: SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.
In ARMv8, the permitted values are 0b0000 and 0b0001.
If the value of ID_AA64ISAR0_EL1.SHA2 is 0b0000, then this field must have the value 0b0000.

AES, bits [7:4]
AES instructions implemented in AArch64 state. Defined values are:
- 0b0000: No AES instructions implemented.
- 0b0001: AESE, AESD, AESMC, and AESIMC instructions implemented.
- 0b0010: As for 0b0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.
In ARMv8, the permitted values are 0b0000, 0b0001, and 0b0010.

Bits [3:0]
Reserved, RES0.

Accessing the ID_AA64ISAR0_EL1
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64ISAR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RO, EL2: RO, EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.52   ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

**Purpose**

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64ISAR1_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64ISAR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>GPI, bits [31:28]</td>
<td>From ARMv8.3: Indicates whether an IMPLEMENTATION DEFINED algorithm is implemented in the PE for generic code authentication, in AArch64 state. Defined values are: 0b0000 Generic Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented. 0b0001 Generic Authentication using an IMPLEMENTATION DEFINED algorithm is implemented. This involves the PACGA instruction. All other values are reserved. From ARMv8.3, the permitted values are 0b0000 and 0b0001. If the value of ID_AA64ISAR1_EL1.GPA is non-zero, this field must have the value 0b0000. Otherwise: Reserved, RES0.</td>
</tr>
<tr>
<td>GPA, bits [27:24]</td>
<td>From ARMv8.3: Indicates whether QARMA or Architected algorithm is implemented in the PE for generic code authentication, in AArch64 state. Defined values are: 0b0000 Generic Authentication using an Architected algorithm is not implemented. 0b0001 Generic Authentication using the QARMA algorithm is implemented. This involves the PACGA instruction. All other values are reserved. From ARMv8.3, the permitted values are 0b0000 and 0b0001. If the value of ID_AA64ISAR1_EL1.GPI is non-zero, this field must have the value 0b0000.</td>
</tr>
</tbody>
</table>
Otherwise:
Reserved, RES0.

LR CPC, bits [23:20]

From ARMv8.4:
Indicates support for weaker release consistency, RCpc based model. Defined values are:
0b0000 The LDAPUR*, STLUR*, and LDAPR* instructions are not implemented.
0b0001 The LDAPR* instructions are implemented.
0b0010 The LDAPUR*, STLUR*, and LDAPR* instructions are implemented.
In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is 0b0000.
In ARMv8.3, the only permitted value is 0b0001. ARMv8.3-RCpc implements the functionality identified by the value 0b0001.
From ARMv8.4, the only permitted value is 0b0010. ARMv8.4-RCpc implements the functionality identified by the value 0b0010.
All other values are reserved.

From ARMv8.3:
Indicates support for weaker release consistency, RCpc based model. Defined values are:
0b0000 The LDAPRB, LDAPRH and LDAPR instructions are not implemented.
0b0001 The LDAPRB, LDAPRH and LDAPR instructions are implemented.
All other values are reserved.
ARMv8.3-RCpc implements the functionality identified by the value 0b0001.
In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is 0b0000.
In ARMv8.3, the only permitted value is 0b0001.
Otherwise:
Reserved, RES0.

FCMA, bits [19:16]

From ARMv8.3:
Indicates support for complex number addition and multiplication, where numbers are stored in vectors. Defined values are:
0b0000 The FCMLA and FCADD instructions are not implemented.
0b0001 The FCMLA and FCADD instructions are implemented.
All other values are reserved.
ARMv8.3-CompNum implements the functionality identified by the value 0b0001.
In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is 0b0000.
From ARMv8.3, the only permitted value is 0b0001.
Otherwise:
Reserved, RES0.

JSCVT, bits [15:12]

From ARMv8.3:
Indicates support for javascript conversion from double precision floating point values to integers in AArch64 state. Defined values are:
0b0000 The FJCVTZS instruction is not implemented.
0b0001 The FJCVTZS instruction is implemented.
All other values are reserved.
ARMv8.3-JSConv implements the functionality identified by 0b0001.
In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is 0b0000.
From ARMv8.3, the only permitted value is 0b0001.

**Otherwise:**
Reserved, RES0.

**API, bits [11:8]**

*From ARMv8.3:*
Indicates whether an IMPLEMENTATION DEFINED algorithm is implemented in the PE for address authentication, in AArch64 state. Defined values are:

- 0b0000 Address Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented.
- 0b0001 Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented. This involves all Pointer Authentication instructions other than the PACGA instruction.

All other values are reserved.
From ARMv8.3, the permitted values are 0b0000 and 0b0001.
If the value of ID_AA64ISAR1_EL1.API is non-zero, this field must have the value 0b0000.

**Otherwise:**
Reserved, RES0.

**APA, bits [7:4]**

*From ARMv8.3:*
Indicates whether QARMA or Architected algorithm is implemented in the PE for address authentication, in AArch64 state. Defined values are:

- 0b0000 Address Authentication using an Architected algorithm is not implemented.
- 0b0001 Address Authentication using the QARMA algorithm is implemented. This involves all Pointer Authentication instructions other than the PACGA instruction.

All other values are reserved.
From ARMv8.3, the permitted values are 0b0000 and 0b0001.
If the value of the ID_AA64ISAR1_EL1.API is non-zero, this field must have the value 0b0000.

**Otherwise:**
Reserved, RES0.

**DPB, bits [3:0]**

*From ARMv8.2:*
Indicates support for the DC CVAP instruction in AArch64 state. Defined values are:

- 0b0000 DC CVAP not supported.
- 0b0001 DC CVAP supported.

All other values are reserved.
ARMv8.2-DCPoP implements the functionality identified by the value 0b0001.
From ARMv8.2 to ARMv8.4, the only permitted values is 0b0001.

**Otherwise:**
Reserved, RES0.

If API == 0000 and APA == 0000, then:
- The TCR_EL1.{TBID,TBID0}, TCR_EL2.{TBID0,TBID1}, TCR_EL2.TBID and TCR_EL3.TBID bits are RES0.
- APIAKeyHi_EL1, APIAKeyLo_EL1, APIBKeyHi_EL1, APIBKeyLo_EL1, APDAKeyHi_EL1, APDAKeyLo_EL1, APDBKeyHi_EL1, APDBKeyLo_EL1 are not allocated.
• SCTLR_ELx.EnIA, SCTLR_ELx.EnIB, SCTLR_ELx.EnDA, SCTLR_ELx.EnDB are all RES0.

If API == 0000 and APA == 0000 and GPI == 0000 and GPA == 0000, then:

• HCR_EL2.APIK and HCR_EL2.API are RES0.

• SCR_EL3.API and SCR_EL3.API are RES0.

### Accessing the ID_AA64ISAR1_EL1

This register can be read using MRS with the following syntax:

\[
\text{MRS } \langle \text{Xt} \rangle, \langle \text{systemreg} \rangle
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64ISAR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>0110</td>
<td></td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.53 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64MMFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64MMFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved (RES0)</td>

</tr>
<tr>
<td></td>
<td></td>
<td>All other values are reserved.</td>
</tr>
</tbody>
</table>
This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not 0b0000.

**SNSMem, bits [15:12]**

Secure versus Non-secure Memory distinction. Defined values are:

- **0b0000**: Does not support a distinction between Secure and Non-secure Memory.
- **0b0001**: Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

**BigEnd, bits [11:8]**

Mixed-endian configuration support. Defined values are:

- **0b0000**: No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
- **0b0001**: Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

All other values are reserved.

**ASIDBits, bits [7:4]**

Number of ASID bits. Defined values are:

- **0b0000**: 8 bits.
- **0b0010**: 16 bits.

All other values are reserved.

**PARange, bits [3:0]**

Physical Address range supported. Defined values are:

- **0b0000**: 32 bits, 4GB.
- **0b0001**: 36 bits, 64GB.
- **0b0010**: 40 bits, 1TB.
- **0b0011**: 42 bits, 4TB.
- **0b0100**: 44 bits, 16TB.
- **0b0101**: 48 bits, 256TB.
- **0b0110**: 52 bits, 4PB.

All other values are reserved.

The value 0b0110 is permitted only if the implementation includes ARMv8.2-LPA, otherwise it is reserved.

**Accessing the ID_AA64MMFR0_EL1**

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Bits [63:32] Reserved, RES0.

XNX, bits [31:28]

*From ARMv8.2:*

Support for execute-never control distinction by Exception level at stage 2. Defined values are:

- `0b0000`: Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
- `0b0001`: Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.

*ARMv8.2-TTS2UXN* implements the functionality identified by the value `0b0001`.

From ARMv8.2, the only permitted value is `0b0001`.

*Otherwise:*

Reserved, RES0.

SpecSEI, bits [27:24]

*When RAS is implemented:*

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches. The defined values of this field are:

- `0b0000`: The PE never generates an SError interrupt due to an External abort on a speculative read.
- `0b0001`: The PE might generate an SError interrupt due to an External abort on a speculative read.

All other values are reserved.

*Otherwise:*

Reserved, RES0. This provides no information about whether the PE generates a speculative SError interrupt.
PAN, bits [23:20]

From ARMv8.1:
Privileged Access Never. Indicates support for the PAN bit in PSTATE, SPSR_EL1, SPSR_EL2, SPSR_EL3, and DSPSR_EL0. Defined values are:
- 0b0000 PAN not supported.
- 0b0001 PAN supported.
- 0b0010 PAN supported and AT S1E1RP and AT S1E1WP instructions supported.

All other values are reserved.

ARMv8.1-PAN implements the functionality identified by the value 0b0001.

ARMv8.2-ATS1E1 implements the functionality added by the value 0b0010.

In ARMv8.1, the only permitted value is 0b0001.
From ARMv8.2, the only permitted value is 0b0010.

Otherwise:
Reserved, RES0.

LO, bits [19:16]

From ARMv8.1:
LORegions. Indicates support for LORegions. Defined values are:
- 0b0000 LORegions not supported.
- 0b0001 LORegions supported.

All other values are reserved.

ARMv8.1-LOR implements the functionality identified by the value 0b0001.

From ARMv8.1, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

HPDS, bits [15:12]

From ARMv8.1:
Hierarchical permission disables bits in translation tables. Defined values are:
- 0b0000 Disabling of hierarchical controls not supported.
- 0b0001 Disabling of hierarchical controls supported with the TCR_EL1.{HPD1, HPD0}, TCR_EL2.HPD or TCR_EL2.{HPD1, HPD0}, and TCR_EL3.HPD bits.
- 0b0010 As for value 0b0001, and adds possible hardware allocation of bits[62:59] of the translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

ARMv8.1-HPD implements the functionality identified by the value 0b0001.

ARMv8.2-TTPBHA implements the functionality identified by the value 0b0010.

From ARMv8.1, the value 0b0000 is not permitted.

Otherwise:
Reserved, RES0.

VH, bits [11:8]

From ARMv8.1:
Virtualization Host Extensions. Defined values are:
- 0b0000 Virtualization Host Extensions not supported.
- 0b0001 Virtualization Host Extensions supported.
All other values are reserved.

ARMv8.1-VHE implements the functionality identified by the value 0b0001.

From ARMv8.1, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

VMIDBits, bits [7:4]

From ARMv8.1:
Number of VMID bits. Defined values are:
0b0000  8 bits
0b0010  16 bits
All other values are reserved.

ARMv8.1-VMID16 implements the functionality identified by the value 0b0010.

From ARMv8.1, the permitted values are 0b0000 and 0b0010.

Otherwise:
Reserved, RES0.

HAFDBS, bits [3:0]

From ARMv8.1:
Hardware updates to Access flag and Dirty state in translation tables. Defined values are:
0b0000   Hardware update of the Access flag and dirty state are not supported.
0b0001   Hardware update of the Access flag is supported.
0b0010   Hardware update of both the Access flag and dirty state is supported.
All other values are reserved.

ARMv8.1-TTHM implements the functionality identified by the values 0b0001 and 0b0010.

From ARMv8.1, the permitted values are 0b0000, 0b0001, and 0b0010.

Otherwise:
Reserved, RES0.

Accessing the ID_AA64MMFR1_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64MMFR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>001</td>
<td>0111</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.55   ID_AA64MMFR2_EL1, AArch64 Memory Model Feature Register 2

The ID_AA64MMFR2_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

This register is present only from ARMv8.2. Otherwise, direct accesses to ID_AA64MMFR2_EL1 are RES0.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.2.

**Attributes**

ID_AA64MMFR2_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64MMFR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
<th>Value 0b0000</th>
<th>Value 0b0001</th>
<th>Value 0b0010</th>
<th>Other Values</th>

</tbody>
</table>

**RES0**

Reserved, RES0.

**BBM, bits [55:52]**

*From ARMv8.4:*

- Allows identification of the requirements of the hardware to have break-before-make sequences when changing block size for a translation.
- 0b0000: Level 0 support for changing block size is supported.
- 0b0001: Level 1 support for changing block size is supported.
- 0b0010: Level 2 support for changing block size is supported.
- All other values are reserved.

ARMv8.4-TTRem implements the functionality identified by the values 0b0000, 0b0001, and 0b0010.

*Otherwise:*

Reserved, RES0.

**TTL, bits [51:48]**

*From ARMv8.4:*

- Indicates support for TTL field in address operations. Defined values are:
  - 0b0000: TLB maintenance instructions by address have bits[47:44] as RES0.
  - 0b0001: TLB maintenance instructions by address have bits[47:44] holding the TTL field.
- All other values are reserved.

ARMv8.4-TTL implements the functionality identified by the value 0b0001.
This field affects TLBI IPAS2E1, TLBI IPAS2E1IS, TLBI IPAS2E1OS, TLBI IPAS2LE1, TLBI IPAS2LE1IS, TLBI IPAS2LE1OS, TLBI VAAE1, TLBI VAAE1IS, TLBI VAAE1OS, TLBI VALE1, TLBI VALE1IS, TLBI VALE1OS, TLBI VALE1, TLBI VALE1IS, TLBI VALE1OS, TLBI VALE2, TLBI VALE2IS, TLBI VALE2OS, TLBI VALE3, TLBI VALE3IS, TLBI VALE3OS,TLBI VALE1, TLBI VALE1IS, TLBI VALE1OS, TLBI VALE2, TLBI VALE2IS, TLBI VALE2OS, TLBI VALE3, TLBI VALE3IS, TLBI VALE3OS.

From ARMv8.4, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

Bits [47:44]
Reserved, RES0.

FWB, bits [43:40]

From ARMv8.4:
Indicates support for HCR_EL2.FWB

0b0000  HCR_EL2.FWB bit is not supported and the field is RES0
0b0001  HCR_EL2.FWB is supported.

If Armv8.4Sec-EL2 is implemented the only permitted value is 0b0001
All other values reserved.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

IDS, bits [39:36]

From ARMv8.4:
Indicates the value of ESR_ELx.EC that reports an exception generated by a read access to the feature ID space. Defined values are:
0b0000  An exception generated by a read access to the feature ID space is reported by ESR_ELx.EC == 0x0.
0b0001  An exception generated by a read access to the feature ID space is reported by ESR_ELx.EC == 0x18.

All other values are reserved.
ARMv8.4-IDST implements the functionality identified by the value 0b0001.
From ARMv8.4, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

AT, bits [35:32]

From ARMv8.4:
Identifies support for unaligned single-copy atomicity and atomic functions. Defined values are:
0b0000  Unaligned single-copy atomicity and atomic functions are not supported.
0b0001  Unaligned single-copy atomicity and atomic functions with a 16-byte address range aligned to 16-bytes are supported.

All other values are reserved.
ARMv8.4-LSE implements the functionality identified by the value 0b0001.
From ARMv8.4, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.
ST, bits [31:28]

**From ARMv8.4:**

Identifies support for small translation tables. Defined values are:

- **0b0000** The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 39.
- **0b0001** The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 48 for 4KB and 16KB granules, and 47 for 64KB granules.

All other values are reserved.

ARMv8.4-TTST implements the functionality identified by the value **0b0001**.

If Armv8.4-SecEL2 is implemented the only permitted value is **0b0001**.

In an implementation which does not support Secure EL2, the permitted values are **0b0000** and **0b0001**.

**Otherwise:**

Reserved, RES0.

NV, bits [27:24]

**From ARMv8.4:**

Nested Virtualization. If EL2 is implemented, indicates support for the use of nested virtualization. Defined values are:

- **0b0000** Nested virtualization is not supported.
- **0b0001** The HCR_EL2.NV, HCR_EL2.NV1, HCR_EL2.AT bits are implemented.
- **0b0010** The VNCR_EL2 register and the HCR_EL2.{AT, NV, NV1, NV2} bits are implemented.

All other values are reserved.

In ARMv8.2, the only permitted value is **0b0000**.

In ARMv8.3, the permitted values are:

- When EL2 is not implemented, **0b0000**.
- When EL2 is implemented, **0b0001**.

The feature ARMv8.3-NV implements the functionality identified by the value **0b0001**.

In ARMv8.4, the permitted values are:

- When EL2 is not implemented, **0b0000**.
- When EL2 is implemented, **0b0010**.

The feature ARMv8.4-NV implements the functionality identified by the value **0b0010**.

**From ARMv8.3:**

Nested Virtualization. If EL2 is implemented, indicates support for the use of nested virtualization. Defined values are:

- **0b0000** Nested virtualization is not supported.
- **0b0001** The HCR_EL2.NV, HCR_EL2.NV1, HCR_EL2.AT bits are implemented.

All other values are reserved.

In ARMv8.2, the only permitted value is **0b0000**.

From ARMv8.3, the permitted values are:

- When EL2 is not implemented, **0b0000**.
- When EL2 is implemented, **0b0001**.

The feature ARMv8.3-NV implements the functionality identified by this value.

**Otherwise:**

Reserved, RES0.
CCIDX, bits [23:20]

*From ARMv8.3:*

Support for the use of revised CCSIDR_EL1 register format. Defined values are:

- 0b0000: 32-bit format implemented for all levels of the CCSIDR_EL1.
- 0b0001: 64-bit format implemented for all levels of the CCSIDR_EL1.

All other values are reserved.

This feature is identified as ARMv8.3-CCIDX.

From ARMv8.3, the permitted values are 0b0000 and 0b0001.

*Otherwise:*

Reserved, RES0.

VARange, bits [19:16]

*From ARMv8.2:*

Indicates support for a larger virtual address. Defined values are:

- 0b0000: VMSA 8-64 supports 48-bit VAs.
- 0b0001: VMSA 8-64 supports 52-bit VAs when using the 64KB translation granule. The other translation granules support 48-bit VAs.

All other values are reserved.

ARMv8.2-LVA implements the functionality identified by the value 0b0001.

From ARMv8.2, the permitted values are 0b0000 and 0b0001.

*Otherwise:*

Reserved, RES0.

IESB, bits [15:12]

*From ARMv8.2:*

Indicates support for the IESB bit in the SCTLR_ELx registers. Defined values are:

- 0b0000: IESB bit in the SCTLR_ELx registers is not supported.
- 0b0001: IESB bit in the SCTLR_ELx registers is supported.

All other values are reserved.

ARMv8.2-IESB implements the functionality identified by the value 0b0001.

From ARMv8.2, the only permitted value is 0b0001.

*Otherwise:*

Reserved, RES0.

LSM, bits [11:8]

*From ARMv8.2:*

Indicates support for LSMAOE and nTLSMD bits in SCTLR_EL1 and SCTLR_EL2. Defined values are:

- 0b0000: LSMAOE and nTLSMD bits not supported.
- 0b0001: LSMAOE and nTLSMD bits supported.

All other values are reserved.

ARMv8.2-LSMAOC implements the functionality identified by the value 0b0001.

*Otherwise:*

Reserved, RES0.
UAO, bits [7:4]

*From ARMv8.2:*

User Access Override. Defined values are:
- 0b0000 UAO not supported.
- 0b0001 UAO supported.

All other values are reserved.

*ARMv8.2-UAO* implements the functionality identified by the value 0b0001.

From ARMv8.2, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

CnP, bits [3:0]

*From ARMv8.2:*

Common not Private translations. Defined values are:
- 0b0000 Common not Private translations not supported.
- 0b0001 Common not Private translations supported.

All other values are reserved.

*ARMv8.2-TTCNP* implements the functionality identified by the value 0b0001.

From ARMv8.2, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

Accessing the ID_AA64MMFR2_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

**Bits [63:52]**

Reserved, RES0.

**DIT, bits [51:48]**

*From ARMv8.4:*

Data Independent Timing. Defined values are:

- 0b0000 AArch64 does not guarantee constant execution time of any instructions.
- 0b0001 AArch64 provides the PSTATE.DIT mechanism to guarantee constant execution time of certain instructions.

All other values are reserved.

ARMv8.4-DIT implements the functionality identified by the value 0b0001.

From ARMv8.4, the only permitted value is 0b0001.

*Otherwise:*

Reserved, RES0.

**AMU, bits [47:44]**

*From ARMv8.4:*

Activity Monitors Extension. Defined values are:

- 0b0000 Activity Monitors Extension is not implemented.
- 0b0001 Activity Monitors Extension Version 1 is implemented.

All other values are reserved.

AMUv1 implements the functionality identified by the value 0b0001.

In ARMv8.0, ARMv8.1, ARMv8.2, and ARMv8.3, the only permitted value is 0b0000.

From ARMv8.4, the permitted values are 0b0000 and 0b0001.

*Otherwise:*

Reserved, RES0.
MPAM, bits [43:40]

From ARMv8.2, or if ARMv8.3 or ARMv8.4:

MPAM Extension. Defined values are:

0b0000 MPAM is not implemented.
0b0001 MPAM is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

SEL2, bits [39:36]

From ARMv8.4:

Secure EL2. Defined values are:

0b0000 Secure EL2 is not implemented.
0b0001 Secure EL2 is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

SVE, bits [35:32]

From ARMv8.2:

Scalable Vector Extension. Defined values are:

0b0000 SVE is not implemented.
0b0001 SVE is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

RAS, bits [31:28]

RAS Extension version. The defined values of this field are:

0b0000 No RAS Extension.
0b0001 RAS Extension present.
0b0010 ARMv8.4-RAS present. As 0b0001, and adds support for:
  • If EL3 is implemented, ARMv8.4-DFE.
  • Additional ERXMISC<:m>_EL1 System registers.
  • Additional System registers ERXPFCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1, and the SCR_EL3.FIEN and HCR_EL2.FIEN trap controls, to support the optional RAS Common Fault Injection Model Extension.

Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS and support for the optional RAS Timestamp and RAS Common Fault Injection Model Extensions.

All other values are reserved.

From ARMv8.4, the only permitted value is 0b0010.

ARMv8.4-RAS implements the functionality identified by the value 0b0010.

In ARMv8.2, the only permitted value is 0b0001.

In ARMv8.1 and ARMv8.0, the permitted values are 0b0000 and 0b0001.
GIC, bits [27:24]
System register GIC interface support. Defined values are:
0b0000  No System register interface to the GIC is supported.
0b0001  System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
All other values are reserved.

AdvSIMD, bits [23:20]
Advanced SIMD. Defined values are:
0b0000  Advanced SIMD is implemented, including support for the following SISD and SIMD operations:
•  Integer byte, halfword, word and doubleword element operations.
•  Single-precision and double-precision floating-point arithmetic.
•  Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001  As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111  Advanced SIMD is not implemented.
All other values are reserved.
This field must have the same value as the FP field.
The permitted values are:
•  0b0000 in an implementation with Advanced SIMD support that does not include the ARMv8.2-FP16 extension.
•  0b0001 in an implementation with Advanced SIMD support that includes the ARMv8.2-FP16 extension.
•  0b1111 in an implementation without Advanced SIMD support.

FP, bits [19:16]
Floating-point. Defined values are:
0b0000  Floating-point is implemented, and includes support for:
•  Single-precision and double-precision floating-point types.
•  Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001  As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111  Floating-point is not implemented.
All other values are reserved.
This field must have the same value as the AdvSIMD field.
The permitted values are:
•  0b0000 in an implementation with floating-point support that does not include the ARMv8.2-FP16 extension.
•  0b0001 in an implementation with floating-point support that includes the ARMv8.2-FP16 extension.
•  0b1111 in an implementation without floating-point support.

EL3, bits [15:12]
EL3 Exception level handling. Defined values are:
0b0000  EL3 is not implemented.
0b0001  EL3 can be executed in AArch64 state only.
0b0010  EL3 can be executed in either AArch64 or AArch32 state.
All other values are reserved.
EL2, bits [11:8]

EL2 Exception level handling. Defined values are:

- 0b0000  EL2 is not implemented.
- 0b0001  EL2 can be executed in AArch64 state only.
- 0b0010  EL2 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL1, bits [7:4]

EL1 Exception level handling. Defined values are:

- 0b0001  EL1 can be executed in AArch64 state only.
- 0b0010  EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL0, bits [3:0]

EL0 Exception level handling. Defined values are:

- 0b0001  EL0 can be executed in AArch64 state only.
- 0b0010  EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

Accessing the ID_AA64PFR0_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_AA64PFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0100</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.57 ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

**Purpose**

Reserved for future expansion of information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AA64PFR1_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64PFR1_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>16</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RAS_frac</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:16]**

Reserved, RES0.

**RAS_frac, bits [15:12]**

*When ARMv8.4-RAS is implemented:*

RAS Extension fractional field.

- **0b0000** If ID_AA64PFR0_EL1.RAS == 0b0001, RAS Extension implemented.
- **0b0001** If ID_AA64PFR0_EL1.RAS == 0b0001, as 0b0000 and adds support for:
  - Additional ERXMISC<m>_EL1 System registers.
  - Additional System registers ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1, and the SCR_EL3.FIEN and HCR_EL2.FIEN trap controls, to support the optional RAS Common Fault Injection Model Extension.

Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS, and support for the optional RAS Timestamp and RAS Common Fault Injection Model Extensions.

All other values are reserved.

This field is valid only if ID_AA64PFR0_EL1.RAS == 0b0001.

*Otherwise:*

Reserved, RES0.

**Bits [11:0]**

Reserved, RES0.

**Accessing the ID_AA64PFR1_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.58  ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0

The ID_AFR0_EL1 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state. Must be interpreted with the Main ID Register, MIDR_EL1. For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_AFR0_EL1[31:0] is architecturally mapped to AArch32 System register ID_AFR0[31:0]. In an implementation that supports only AArch64 state, this register is UNKNOWN. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_AFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AFR0_EL1 bit assignments are:

```
63 16 15 12 11 8 7 4 3 0
  RES0
  ??
```

**Bits [63:16]**

<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.59  ID_DFR0_EL1, AArch32 Debug Feature Register 0

The ID_DFR0_EL1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, MIDR_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_DFR0_EL1[31:0] is architecturally mapped to AArch32 System register ID_DFR0[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_DFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_DFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31:28</td>

</tr>
<tr>
<td>19:16</td>
<td>MMapTrc</td>
</tr>
<tr>
<td>15:12</td>
<td>CopTrc</td>
</tr>
<tr>
<td>11:8</td>
<td>MMapDbg</td>
</tr>
<tr>
<td>7:4</td>
<td>CopSdbg</td>
</tr>
<tr>
<td>3:0</td>
<td>CopDbg</td>
</tr>
</tbody>
</table>

**RES0**

Reserved, RES0.

**TraceFilt, bits [31:28]**

ARMv8.4 Self-hosted Trace Extension version. Defined values are:

- 0b0000  ARMv8.4 Self-hosted Trace Extension not implemented.
- 0b0001  ARMv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

ARMv8.4-Trace implements the functionality added by the value 0b0001.

From ARMv8.3, the permitted values are 0b0000 and 0b0001.

**PerfMon, bits [27:24]**

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the Alternative ID scheme described in Alternative ID scheme used for the Performance Monitors Extension version on page D12-2682.

Defined values are:

- 0b0000  Performance Monitors Extension not implemented.
- 0b0001  Performance Monitors Extension version 1 implemented, PMUv1.
- 0b0010  Performance Monitors Extension version 2 implemented, PMUv2.
- 0b0011  Performance Monitors Extension version 3 implemented, PMUv3.
- 0b0100  PMUv3 for ARMv8.1. As 0b0011, and also includes support for:
  - Extended 16-bit PMEVTYPE<n>.evtCount field.
  - If EL2 is implemented, the HDCR.HPMD control bit.
0b101   PMUv3 for ARMv8.4. As 0b0100 and also includes support for the PMMIR register.
0b111   IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value in new implementations.

ARMv8.1-PMU implements the functionality added by the value 0b0100.
ARMv8.4-PMU implements the functionality added by the value 0b0101.
All other values are reserved.
In any ARMv8 implementation, the values 0b0001 and 0b0010 are not permitted.
From ARMv8.1, the value 0b0011 is not permitted.
From ARMv8.4, the value 0b1000 is not permitted.

Note
In ARMv7, the value 0b0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

MProfDbg, bits [23:20]
M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:
0b0000   Not supported.
0b0001   Support for M profile Debug architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A, the only permitted value is 0b0000.

MMapTrc, bits [19:16]
Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:
0b0000   Not supported.
0b0001   Support for ARM trace architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.
See the ETM Architecture Specification for more information.

CopTrc, bits [15:12]
Support for System registers-based trace model, using registers in the coproc == 0b1110 encoding space. Defined values are:
0b0000   Not supported.
0b0001   Support for ARM trace architecture, with System registers access.
All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.
See the ETM Architecture Specification for more information.

MMapDbg, bits [11:8]
Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.
In ARMv8-A, this field is RES0.
The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSdbg, bits [7:4]
Support for a System registers-based Secure debug model, using registers in the coproc = 0b1110 encoding space, for an A profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-secure state, this field is RES0. Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]
Support for System registers-based debug model, using registers in the coproc == 0b1110 encoding space, for A and R profile processors. Defined values are:
- 0b0000 Not supported.
- 0b0010 Support for ARMv6, v6 Debug architecture, with System registers access.
- 0b0011 Support for ARMv6, v6.1 Debug architecture, with System registers access.
- 0b0100 Support for ARMv7, v7 Debug architecture, with System registers access.
- 0b0101 Support for ARMv7, v7.1 Debug architecture, with System registers access.
- 0b0110 Support for ARMv8 debug architecture, with System registers access.
- 0b0111 Support for ARMv8 debug architecture, with System registers access, and Virtualization Host extensions.
- 0b1000 Support for ARMv8.2 debug architecture.
- 0b1001 Support for ARMv8.4 debug architecture.
All other values are reserved.
In any ARMv8 implementation, the values 0b0000, 0b0010, 0b0011, 0b0100, and 0b0101 are not permitted.
If ARMv8.1-VHE is not implemented, the only permitted value is 0b0110.
In an ARMv8.0 implementation, the value 0b1000 is not permitted.

Accessing the ID_DFR0_EL1
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_DFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>010</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If \((\text{SCR}_\text{EL3}).\text{NS} == 1 \lor \text{SCR}_\text{EL3}).\text{EEL2} == 1\) \&\& \text{IsUsingAAArch64}(\text{EL2}) \&\& \text{HCR}_\text{EL2}.\text{TID3} == 1\), then read accesses at EL1 are trapped to EL2.
D12.2.60  ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0

The ID_ISAR0_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_ISAR0_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR0[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISAR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:28]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Divide, bits [27:24]</td>
<td>Indicates the implemented Divide instructions. Defined values are:</td>
</tr>
<tr>
<td>Debug, bits [23:20]</td>
<td>Indicates the implemented Debug instructions. Defined values are:</td>
</tr>
<tr>
<td>Coproc, bits [19:16]</td>
<td>Indicates the implemented System register access instructions. Defined values are:</td>
</tr>
</tbody>
</table>

Reserved, RES0.

Indicates the implemented Divide instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds SDIV and UDIV in the T32 instruction set.
- 0b0010: As for 0b0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0010.

Indicates the implemented Debug instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds BKPT.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0001.

Indicates the implemented System register access instructions. Defined values are:

- 0b0000: None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.
- 0b0001: Adds generic CDP, LDC, MCR, MRC, and STC.
0b0010 As for 0b0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.
0b0011 As for 0b0010, and adds generic MCRR and MRRC.
0b0000 As for 0b0011, and adds generic MCRR2 and MRRC2.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0000.

### CmpBranch, bits [15:12]
Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds CBNZ and CBZ.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

### BitField, bits [11:8]
Indicates the implemented BitField instructions. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds BFC, BFI, SBFX, and UBFX.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

### BitCount, bits [7:4]
Indicates the implemented Bit Counting instructions. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds CLZ.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

### Swap, bits [3:0]
Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds SWP and SWPB.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0000.

### Accessing the ID_ISAR0_EL1
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
### D12.2.61 ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1

The ID_ISAR1_EL1 characteristics are:

#### Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

#### Configurations

AArch64 System register ID_ISAR1_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR1[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes

ID_ISAR1_EL1 is a 64-bit register.

#### Field descriptions

The ID_ISAR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value 1</th>
<th>Value 2</th>
<th>Value 3</th>
<th>Value 4</th>

<td></td>
</tr>
</tbody>
</table>

#### Bits [63:32]

Reserved, RES0.

#### Jazelle, bits [31:28]

Indicates the implemented Jazelle extension instructions. Defined values are:

- 0b0000: No support for Jazelle.
- 0b0001: Adds the BXJ instruction and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0001.

#### Interwork, bits [27:24]

Indicates the implemented Interworking instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the BX instruction, and the T bit in the PSR.
- 0b0010: As for 0b0001, and adds the BLX instruction. PC loads have BX-like behavior.
- 0b0011: As for 0b0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0011.
Immediate, bits [23:20]
Indicates the implemented data-processing instructions with long immediates. Defined values are:

- **0b0000** None implemented.
- **0b0001** Adds:
  - The MOVT instruction.
  - The MOV instruction encodings with zero-extended 16-bit immediates.
  - The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.
In ARMv8-A, the only permitted value is **0b0001**.

IfThen, bits [19:16]
Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:

- **0b0000** None implemented.
- **0b0001** Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.
In ARMv8-A, the only permitted value is **0b0001**.

Extend, bits [15:12]
Indicates the implemented Extend instructions. Defined values are:

- **0b0000** No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
- **0b0001** Adds the SXTB, SXTH, UXTB, and UXTH instructions.
- **0b0010** As for **0b0001**, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.
In ARMv8-A, the only permitted value is **0b0010**.

Except_AR, bits [11:8]
Indicates the implemented A and R profile exception-handling instructions. Defined values are:

- **0b0000** None implemented.
- **0b0001** Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.
In ARMv8-A, the only permitted value is **0b0001**.

Except, bits [7:4]
Indicates the implemented exception-handling instructions in the A32 instruction set. Defined values are:

- **0b0000** Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
- **0b0001** Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.
In ARMv8-A, the only permitted value is **0b0001**.

Endian, bits [3:0]
Indicates the implemented Endian instructions. Defined values are:

- **0b0000** None implemented.
Accessing the ID_ISAR1_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>001</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.62 ID_ISR2_EL1, AArch32 Instruction Set Attribute Register 2

The ID_ISR2_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISR0_EL1, ID_ISR1_EL1, ID_ISR3_EL1, ID_ISR4_EL1, and ID_ISR5_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_ISR2_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISR2[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISR2_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Reversal</td>
<td>Indicates the implemented Reversal instructions. Defined values are:</td>
</tr>
<tr>

<td>All other values are reserved.</td>
</tr>
<tr>
<td></td>
<td>In ARMv8-A the only permitted value is 0b0001.</td>
</tr>
<tr>
<td></td>
<td>The exception return forms of the data-processing instructions are:</td>
</tr>
<tr>
<td></td>
<td>• In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.</td>
</tr>
</tbody>
</table>
In the T32 instruction set, the SUBS PC,LR,#N instruction.

**MultU, bits [23:20]**
Indicates the implemented advanced unsigned Multiply instructions. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds the UMULL and UMLAL instructions.
- 0b0010 As for 0b0001, and adds the UMAAL instruction.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0010.

**MultS, bits [19:16]**
Indicates the implemented advanced signed Multiply instructions. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds the SMULL and SMLAL instructions.
- 0b0010 As for 0b0001, and adds the SMLAB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
- 0b0011 As for 0b0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSDX, SMLSLD, SMLSLDX, SMLLA, SMLLAR, SMMLS, SMMLSR, SMMLUL, SMMLUR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0011.

**Mult, bits [15:12]**
Indicates the implemented additional Multiply instructions. Defined values are:
- 0b0000 No additional instructions implemented. This means only MUL is implemented.
- 0b0001 Adds the MLA instruction.
- 0b0010 As for 0b0001, and adds the MLS instruction.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0010.

**MultiAccessInt, bits [11:8]**
Indicates the support for interruptible multi-access instructions. Defined values are:
- 0b0000 No support. This means the LDM and STM instructions are not interruptible.
- 0b0001 LDM and STM instructions are restartable.
- 0b0010 LDM and STM instructions are continuable.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0000.

**MemHint, bits [7:4]**
Indicates the implemented Memory Hint instructions. Defined values are:
- 0b0000 None implemented.
- 0b0001 Adds the PLD instruction.
- 0b0010 Adds the PLD instruction. (0b0000 and 0b0010 have identical effects.)
- 0b0011 As for 0b0001 (or 0b0010), and adds the PLI instruction.
- 0b0100 As for 0b0011, and adds the PLDW instruction.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0100.
LoadStore, bits [3:0]

Indicates the implemented additional load/store instructions. Defined values are:

- 0b0000: No additional load/store instructions implemented.
- 0b0001: Adds the LDRD and STRD instructions.
- 0b0010: As for 0b0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0010.

Accessing the ID_ISAR2_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR2_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>010</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
<td>RO</td>
<td>n/a</td>
<td>RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.63   ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_ISAR3_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR3[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR3_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISAR3_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>T32EE, bits [31:28]</td>
<td>Indicates the implemented T32EE instructions. Defined values are:</td>
</tr>
<tr>
<td>False</td>
<td>None implemented.</td>
</tr>
<tr>
<td>True</td>
<td>Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking. All other values are reserved. In ARMv8-A, the only permitted value is 0b0000.</td>
</tr>
<tr>
<td>TrueNOP, bits [27:24]</td>
<td>Indicates the implemented true NOP instructions. Defined values are:</td>
</tr>
<tr>
<td>False</td>
<td>None implemented. This means there are no NOP instructions that do not have any register dependencies.</td>
</tr>
<tr>
<td>True</td>
<td>Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints. All other values are reserved. In ARMv8-A, the only permitted value is 0b0001.</td>
</tr>
<tr>
<td>T32Copy, bits [23:20]</td>
<td>Indicates the support for T32 non flag-setting MOV instructions. Defined values are:</td>
</tr>
<tr>
<td>False</td>
<td>Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.</td>
</tr>
</tbody>
</table>
0b0001  Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

**TabBranch, bits [19:16]**
Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

0b0000  None implemented.
0b0001  Adds the TBB and TBH instructions.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

**SynchPrim, bits [15:12]**
Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

0b0000  If SynchPrim_frac == 0b0000, no Synchronization Primitives implemented.
0b0001  If SynchPrim_frac == 0b0000, adds the LDREX and STREX instructions.
0b0001  If SynchPrim_frac == 0b0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.
0b0010  If SynchPrim_frac == 0b0000, as for [0b0001, 0b0011] and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.
In ARMv8-A, the only permitted value is 0b0010.

**SVC, bits [11:8]**
Indicates the implemented SVC instructions. Defined values are:

0b0000  Not implemented.
0b0001  Adds the SVC instruction.

All other values are reserved.
In ARMv8-A, the only permitted value is 0b0001.

**SIMD, bits [7:4]**
Indicates the implemented SIMD instructions. Defined values are:

0b0000  None implemented.
0b0001  Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
0b0011  As for 0b0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.
In ARMv8-A the only permitted value is 0b0011.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports floating-point and Advanced SIMD instructions, **MVFR0, MVFR1, and MVFR2** give information about the implemented Advanced SIMD instructions.
Saturate, bits [3:0]
Indicates the implemented Saturate instructions. Defined values are:

- **0b0000** None implemented. This means no non-Advanced SIMD saturate instructions are implemented.
- **0b0001** Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs. All other values are reserved.

In ARMv8-A, the only permitted value is **0b0001**.

**Accessing the ID_ISAR3_EL1**
This register can be read using MRS with the following syntax:

`MRS <Xt>, <systemreg>`

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR3_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>011</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
### ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_ISAR4_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR4[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR4_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISAR4_EL1 bit assignments are:

![Bit Assignment Diagram]

- **Bits [63:32]**
  - Reserved, RES0.

- **SWP_frac, bits [31:28]**
  - Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:
    - 0b0000: SWP or SWPB instructions not implemented.
    - 0b0001: SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.
  - All other values are reserved. This field is valid only if the ID_ISAR0.Swap_instrs field is 0b0000. In ARMv8-A, the only permitted value is 0b0000.

- **PSR_M, bits [27:24]**
  - Indicates the implemented M profile instructions to modify the PSRs. Defined values are:
    - 0b0000: None implemented.
    - 0b0001: Adds the M profile forms of the CPS, MRS, and MSR instructions.
  - All other values are reserved.
  - In ARMv8-A, the only permitted value is 0b0000.
SynchPrim_frac, bits [23:20]

Used in conjunction with ID_ISAR3.SyncPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- **0b0000**: If SynchPrim == 0b0000, no Synchronization Primitives implemented. If SynchPrim == 0b0001, adds the LDREX and STREX instructions. If SynchPrim == 0b0100, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.
- **0b0011**: If SynchPrim == 0b0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A, the only permitted value is 0b0000.

Barrier, bits [19:16]

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:

- **0b0000**: None implemented. Barrier operations are provided only as System instructions in the (coproc==0b1111) encoding space.
- **0b0001**: Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0001.

SMC, bits [15:12]

Indicates the implemented SMC instructions. Defined values are:

- **0b0000**: None implemented.
- **0b0001**: Adds the SMC instruction.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0001 and 0b0000.

If EL1 cannot use AArch32, then this field has the value 0b0000.

Writeback, bits [11:8]

Indicates the support for Writeback addressing modes. Defined values are:

- **0b0000**: Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- **0b0001**: Adds support for all of the writeback addressing modes.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0001.

WithShifts, bits [7:4]

Indicates the support for instructions with shifts. Defined values are:

- **0b0000**: Nonzero shifts supported only in MOV and shift instructions.
- **0b0001**: Adds support for shifts of loads and stores over the range LSL 0-3.
- **0b0011**: As for 0b0001, and adds support for other constant shift options, both on load/store and other instructions.
- **0b0100**: As for 0b0011, and adds support for register-controlled shift options.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0100.
Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Defined values are:

- **0b0000**: None implemented. No T variant instructions are implemented.
- **0b0001**: Adds the LDRBT, LDRT, STRBT, and STRT instructions.
- **0b0010**: As for 0b0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

In ARMv8-A, the only permitted value is **0b0010**.

**Accessing the ID_ISAR4_EL1**

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR4_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>100</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RO, EL1: n/a, EL2: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.65  ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5

The ID_ISAR5_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR4_EL1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_ISAR5_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR5[31:0].

In an implementation that supports only AArch64 state, this register is **UNKNOWN**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

ID_ISAR5_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISAR5_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>RES0</td>
</tr>
<tr>
<td>31-28</td>
<td>VCMA</td>
</tr>
<tr>

**Bits [63:32]**

Reserved, RES0.

**VCMA, bits [31:28]**

*From ARMv8.3:*

Indicates AArch32 support for complex number addition and multiplication where numbers are stored in vectors. Defined values are:

- **0b0000** The VCMLA and VCADD instructions are not implemented in AArch32.
- **0b0001** The VCMLA and VCADD instructions are implemented in AArch32.

All other values are reserved.

ARMv8.3-CompNum implements the functionality identified by **0b0001**.

In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is **0b0000**.

From ARMv8.3, the only permitted value is **0b0001**.

*Otherwise:*

Reserved, RES0.

**RDM, bits [27:24]**

*From ARMv8.1:*

Indicates whether the VQRDMLAH and VQRDMLSH instructions are implemented in AArch32 state. Defined values are:

- **0b0000** No VQRDMLAH and VQRDMLSH instructions implemented.
- **0b0001** VQRDMLAH and VQRDMLSH instructions implemented.
All other values are reserved.

**ARMv8.1-RDMA** implements the functionality identified by the value 0b0001.

In ARMv8.0, the only permitted value is 0b0000.

From ARMv8.1, the only permitted value is 0b0001.

**Otherwise:**

Reserved, RES0.

**Bits [23:20]**

Reserved, RES0.

**CRC32, bits [19:16]**

Indicates whether the CRC32 instructions are implemented in AArch32 state.

- 0b0000 No CRC32 instructions implemented.
- 0b0001 CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

In ARMv8.0, the permitted values are 0b0000 and 0b0001.

From ARMv8.1, the only permitted value is 0b0001.

**SHA2, bits [15:12]**

Indicates whether the SHA2 instructions are implemented in AArch32 state.

- 0b0000 No SHA2 instructions implemented.
- 0b0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**SHA1, bits [11:8]**

Indicates whether the SHA1 instructions are implemented in AArch32 state.

- 0b0000 No SHA1 instructions implemented.
- 0b0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**AES, bits [7:4]**

Indicates whether the AES instructions are implemented in AArch32 state.

- 0b0000 No AES instructions implemented.
- 0b0001 AESE, AESD, AESMC, and AESIMC implemented.
- 0b0010 As for 0b0001, plus VMULL (polynomial) instructions operating on 64-bit data quantities.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0000 and 0b0010.

**SEVL, bits [3:0]**

Indicates whether the SEVL instruction is implemented in AArch32 state.

- 0b0000 SEVL is implemented as a NOP.
- 0b0001 SEVL is implemented as Send Event Local.

All other values are reserved.

In ARMv8-A, the only permitted value is 0b0001.
Accessing the ID_ISAR5_EL1

This register can be read using MRS with the following syntax:

\[ \text{MRS} <Xt>, \text{<systemreg>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR5_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>101</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
<td>RO</td>
<td>n/a</td>
<td>RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If \((\text{SCR_EL3.NS} == 1 || \text{SCR_EL3.EEL2} == 1) && \text{IsUsingAArch64(EL2)} && \text{HCR_EL2.TID3} == 1\), then read accesses at EL1 are trapped to EL2.
D12.2.66  ID_ISAR6_EL1, AArch32 Instruction Set Attribute Register 6

The ID_ISAR6_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1 and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_ISAR6_EL1[31:0] is architecturally mapped to AArch32 System register ID_ISAR6[31:0].

This register is present only from ARMv8.2. Otherwise, direct accesses to ID_ISAR6_EL1 are RES0.

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.2.

**Attributes**

ID_ISAR6_EL1 is a 64-bit register.

**Field descriptions**

The ID_ISAR6_EL1 bit assignments are:

![Diagram of ID_ISAR6_EL1 bit assignments]

**Bits [63:12]**

Reserved, RES0.

**FHM, bits [11:8]**

Indicates whether VFMAL and VFMSL instructions are implemented.

- 0b0000  VFMAL and VFMSL instructions are not implemented.
- 0b0001  VFMAL and VFMSL instructions are implemented.

ARMv8.2-FHM implements the functionality identified by the value 0b0001.

In ARMv8.0 and ARMv8.1, the only permitted value is 0b0000.

In ARMv8.2, the permitted values are 0b0000 and 0b0001.

**DP, bits [7:4]**

Indicates the support for dot product instructions in AArch32 state.

- 0b0000  No dot product instructions are implemented.
- 0b0001  VUDOT and VSDOT instructions are implemented.

All other values are reserved.

ARMv8.2-DotProd implements the functionality identified by the value 0b0001.

In ARMv8.0 and ARMv8.1, the only permitted value is 0b0000.

In ARMv8.2, the permitted values are 0b0000 and 0b0001.
JSCVT, bits [3:0]

From ARMv8.3:
Indicates whether the Javascript conversion instruction is implemented in AArch32 state. Defined values are:
- 0b0000: The VJCVT instruction is not implemented.
- 0b0001: The VJCVT instruction is implemented.
All other values are reserved.
ARMv8.3-JSConv implements the functionality identified by 0b0001.
In ARMv8.0, ARMv8.1, and ARMv8.2, the only permitted value is 0b0000.
From ARMv8.3, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

Accessing the ID_ISAR6_EL1
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_ISAR6_EL1</td>
<td>0000</td>
<td>11</td>
<td>000</td>
<td>111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.67  ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0

The ID_MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

Configurations

AArch64 System register ID_MMFR0_EL1[31:0] is architecturally mapped to AArch32 System register ID_MMFR0[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ID_MMFR0_EL1 is a 64-bit register.

Field descriptions

The ID_MMFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit position</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>RES0</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>32-31</td>

<tr>
<td>7-4</td>
<td>PMSA</td>
<td></td>
</tr>
<tr>
<td>3-0</td>
<td>VMSA</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- 0b0000: Implemented as Non-cacheable.
- 0b0001: Implemented with hardware coherency support.
- 0b1111: Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0b0000, 0b0001, and 0b1111.

This field is valid only if the implementation supports two levels of shareability, as indicated by ID_MMFR0_EL1.ShareLvl having the value 0b0001.

When ID_MMFR0_EL1.ShareLvl is zero, this field is UNK.

FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Defined values are:

- 0b0000: Not supported.
- 0b0001: Support for FCSE.

All other values are reserved.

In ARMv8 the only permitted value is 0b0000.
AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>None supported.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Support for Auxiliary Control Register only.</td>
</tr>
<tr>
<td>0b0010</td>
<td>Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary</td>
</tr>
<tr>
<td></td>
<td>Control Register.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8 the only permitted value is 0b0010.

--- Note ---

Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.</td>
</tr>
<tr>
<td>0b0010</td>
<td>Support for TCM only, ARMv6 implementation.</td>
</tr>
<tr>
<td>0b0011</td>
<td>Support for TCM and DMA, ARMv6 implementation.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.

ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>One level of shareability implemented.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Two levels of shareability implemented.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8 the only permitted value is 0b0001.

OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Implemented as Non-cacheable.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Implemented with hardware coherency support.</td>
</tr>
<tr>
<td>0b1111</td>
<td>Shareability ignored.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8 the permitted values are 0b0000, 0b0001, and 0b1111.

PMSA, bits [7:4]

Indicates support for a PMSA. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Support is IMPLEMENTATION DEFINED PMSA.</td>
</tr>
<tr>
<td>0b0010</td>
<td>Support for PMSAv6, with a Cache Type Register implemented.</td>
</tr>
<tr>
<td>0b0011</td>
<td>Support for PMSAv7, with support for memory subsections. ARMv7-R profile.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.
VMSA, bits [3:0]

Indicates support for a VMSA. Defined values are:

- 0b0000: Not supported.
- 0b0001: Support for IMPLEMENTATION DEFINED VMSA.
- 0b0010: Support for VMSAv6, with Cache and TLB Type Registers implemented.
- 0b0011: Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
- 0b0100: As for 0b0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
- 0b0101: As for 0b0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.
In ARMv8-A the only permitted value is 0b0101.

Accessing the ID_MMFR0_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_MMFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>100</td>
<td>001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.68 ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1

The ID_MMFR1_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_MMFR1_EL1[31:0] is architecturally mapped to AArch32 System register ID_MMFR1[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR1_EL1 is a 64-bit register.

**Field descriptions**

The ID_MMFR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>RES0</th>
<th>BPred</th>
<th>L1TstCln</th>
<th>L1Uni</th>
<th>L1Hvd</th>
<th>L1UniSW</th>
<th>L1HvdSW</th>
<th>L1UniVA</th>
<th>L1HvdVA</th>
</tr>
</thead>
</table>

**RES0**

Reserved, RES0.

**BPred, bits [31:28]**

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

- **00000** No branch predictor, or no MMU present. Implies a fixed MPU configuration.

- **00001** Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Changes to the TTBR0, TTBR1, or TTBCR registers.
  - Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.

- **00010** Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Changes to the TTBR0, TTBR1, or TTBCR registers.
  - Any change to the TTBR0, TTBR1, or TTBCR registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.

- **00011** Branch predictor requires flushing only on writing new data to instruction locations.

- **00100** For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.
In ARMv8-A the permitted values are 0b0010, 0b0011, or 0b0100. For values other than 0b0000 and 0b0100 the ARM Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.

**L1TstCln, bits [27:24]**

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported Level 1 data cache test and clean operations are:
  - Test and clean data cache.
- 0b0010 As for 0001, and adds:
  - Test, clean, and invalidate data cache.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.

**L1Uni, bits [23:20]**

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported entire Level 1 cache operations are:
  - Invalidate cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- 0b0010 As for 0001, and adds:
  - Clean cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.

**L1Hvd, bits [19:16]**

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported entire Level 1 cache operations are:
  - Invalidate instruction cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- 0b0010 As for 0001, and adds:
  - Invalidate data cache.
  - Invalidate data cache and instruction cache, including branch predictor if appropriate.
- 0b0011 As for 0010, and adds:
  - Clean data cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.
L1UniSW, bits [15:12]
Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>None supported.</td>

</tr>
</tbody>
</table>
D12 AArch64 System Register Descriptions
D12.2 General system control registers

- Clean and invalidate data cache line by VA.
- Clean instruction cache line by VA.

0b0010  As for 0001, and adds:
- Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0b0000.

Accessing the ID_MMFR1_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_MMFR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>101</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.69   ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2

The ID_MMFR2_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_MMFR2_EL1[31:0] is architecturally mapped to AArch32 System register ID_MMFR2[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR2_EL1 is a 64-bit register.

**Field descriptions**

The ID_MMFR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>HWAccFlg</td>
<td>Hardware Access Flag. In earlier versions of the ARM Architecture, this field indicates support for a Hardware Access flag, as part of the VMSA\text{v}7 implementation. Defined values are:</td>
</tr>
<tr>
<td></td>
<td>0b0000 Not supported.</td>
</tr>
<tr>
<td></td>
<td>0b0001 Support for VMSA\text{v}7 Access flag, updated in hardware.</td>
</tr>
<tr>
<td></td>
<td>All other values are reserved.</td>
</tr>
<tr>
<td></td>
<td>In ARMv8 the only permitted value is 0b0000.</td>
</tr>
<tr>
<td>WFIStall</td>
<td>Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:</td>
</tr>
<tr>
<td></td>
<td>0b0000 Not supported.</td>
</tr>
<tr>
<td></td>
<td>0b0001 Support for WFI stalling.</td>
</tr>
<tr>
<td></td>
<td>All other values are reserved.</td>
</tr>
<tr>
<td></td>
<td>In ARMv8 the permitted values are 0b0000 and 0b0001.</td>
</tr>
<tr>
<td>MemBarr</td>
<td>Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc==0b1111) encoding space:</td>
</tr>
<tr>
<td></td>
<td>0b0000 None supported.</td>
</tr>
</tbody>
</table>

\[ \text{0b0001} \] Supported memory barrier System instructions are:
- Data Synchronization Barrier (DSB).

\[ \text{0b0010} \] As for 0001, and adds:
- Instruction Synchronization Barrier (ISB).
- Data Memory Barrier (DMB).

All other values are reserved.

In ARMv8 the only permitted value is \[ \text{0b0010} \].

ARM deprecates the use of these operations. ID_ISAR4.Barrier_instrs indicates the level of support for the preferred barrier instructions.

**UniTLB, bits [19:16]**

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

\[ \text{0b0000} \] Not supported.

\[ \text{0b0001} \] Supported unified TLB maintenance operations are:
- Invalidate all entries in the TLB.
- Invalidate TLB entry by VA.

\[ \text{0b0010} \] As for 0001, and adds:
- Invalidate TLB entries by ASID match.

\[ \text{0b0011} \] As for 0010, and adds:
- Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.

\[ \text{0b0100} \] As for 0011, and adds:
- Invalidate Hyp mode unified TLB entry by VA.
- Invalidate entire Non-secure PL1&0 unified TLB.
- Invalidate entire Hyp mode unified TLB.

\[ \text{0b0101} \] As for 0b100, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, TLBIMVALH.

\[ \text{0b0110} \] As for 0b101, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.

All other values are reserved.

In ARMv8-A the only permitted value is \[ \text{0b0110} \].

**HvdTLB, bits [15:12]**

If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

**L1HvdRng, bits [11:8]**

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

\[ \text{0b0000} \] Not supported.

\[ \text{0b0001} \] Supported Level 1 Harvard cache maintenance range operations are:
- Invalidate data cache range by VA.
- Invalidate instruction cache range by VA.
- Clean data cache range by VA.
- Clean and invalidate data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is \[ \text{0b0000} \].
L1HvdBG, bits [7:4]

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:

0b0000  Not supported.
0b0001  Supported Level 1 Harvard cache background fetch operations are:
  • Fetch instruction cache range by VA.
  • Fetch data cache range by VA.

All other values are reserved.
In ARMv8 the only permitted value is 0b0000.

L1HvdFG, bits [3:0]

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:

0b0000  Not supported.
0b0001  Supported Level 1 Harvard cache foreground fetch operations are:
  • Fetch instruction cache range by VA.
  • Fetch data cache range by VA.

All other values are reserved.
In ARMv8 the only permitted value is 0b0000.

Accessing the ID_MMFR2_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_MMFR2_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>110</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If \( \text{SCR EL3.NS} = 1 \) \( \lor \) \( \text{SCR EL3.EEL2} = 1 \) \&\& \text{IsUsingAArch64(EL2)} \&\& \text{HCR_EL2.TID3} = 1 \), then read accesses at EL1 are trapped to EL2.
D12.2.70   ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3

The ID_MMFR3_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, and ID_MMFR4_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_MMFR3_EL1[31:0] is architecturally mapped to AArch32 System register ID_MMFR3[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR3_EL1 is a 64-bit register.

**Field descriptions**

The ID_MMFR3_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Field descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 32 31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</td>
<td>RES0 Supersec CMemSz CohWalk PAN MaintBcst BPMaint CMaintSW CMaintVA</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**Supersec, bits [31:28]**

Supersections. On a VMSA implementation, indicates whether Supersections are supported.

Defined values are:

- 0b0000  Supersections supported.
- 0b1111  Supersections not supported.

All other values are reserved.

In ARMv8-A the permitted values are 0b0000 and 0b1111.

**CMemSz, bits [27:24]**

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

- 0b0000  4GB, corresponding to a 32-bit physical address range.
- 0b0001  64GB, corresponding to a 36-bit physical address range.
- 0b0010  1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

In ARMv8-A the permitted values are 0b0000, 0b0001, and 0b0010.
CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the Point of Unification. Defined values are:

- 0b0000 Updates to the translation tables require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.
- 0b0001 Updates to the translation tables do not require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0001.

PAN, bits [19:16]

*From ARMv8.1:*

Privileged Access Never. Indicates support for the PAN bit in CPSR, SPSR, and DSPSR in AArch32 state. Defined values are:

- 0b0000 PAN not supported.
- 0b0001 PAN supported.
- 0b0010 PAN supported and ATS1CPRP and ATS1CPWP instructions supported.

All other values are reserved.

ARMv8.1-PAN implements the functionality identified by the value 0b0001.

ARMv8.2-ATS1E1 implements the functionality added by the value 0b0010.

In ARMv8.1 the value 0b0000 is not permitted.

From ARMv8.2, the only permitted value is 0b0010.

*Otherwise:*

Reserved, RES0.

MaintBest, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:

- 0b0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0b0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0b0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0010.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- 0b0010 As for 0001, and adds:
  - Invalidate branch predictors by VA.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0010.
CMaintSW, bits [7:4]
Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported hierarchical cache maintenance instructions by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0001.
In a unified cache implementation, the data cache maintenance operations apply to the unified caches.

CMaintVA, bits [3:0]
Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported hierarchical cache maintenance operations by VA are:
  - Invalidate data cache by VA.
  - Clean data cache by VA.
  - Clean and invalidate data cache by VA.
  - Invalidate instruction cache by VA.
  - Invalidate all instruction cache entries.
All other values are reserved.
In ARMv8-A the only permitted value is 0b0001.
In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

Accessing the ID_MMFR3_EL1
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.71 ID_MMFR4_EL1, AArch32 Memory Model Feature Register 4

The ID_MMFR4_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, and ID_MMFR3_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_MMFR4_EL1[31:0] is architecturally mapped to AArch32 System register ID_MMFR4[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR4_EL1 is a 64-bit register.

**Field descriptions**

The ID_MMFR4_EL1 bit assignments are:

<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:28]**

Reserved, RES0.

**CCIDX, bits [27:24]**

*From ARMv8.3:*

Support for use of the revised CCSIDR format and the presence of the CCSIDR2 is indicated.

Defined values are:

- \( \text{0b0000} \) 32-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is not implemented.
- \( \text{0b0001} \) 64-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is implemented.

All other values are reserved.

From ARMv8.3, the permitted values are \( \text{0b0000} \) and \( \text{0b0001} \). This feature is identified as ARMv8.3-CCIDX.

*From ARMv8.2, or if ARMv8.1 or ARMv8.0:*

Reserved, RAZ.

**Otherwise:**

Reserved, RES0.
LSM, bits [23:20]

From ARMv8.2:
Indicates support for LSMAOE and nTLSMD bits in HSCTLR and SCTLR. Defined values are:

- **0b0000**: LSMAOE and nTLSMD bits not supported.
- **0b0001**: LSMAOE and nTLSMD bits supported.

All other values are reserved.

**ARMv8.2-LSMAOC** implements the functionality identified by the value **0b0001**.

From ARMv8.1, or if ARMv8.0:
Reserved, RAZ.

Otherwise:
Reserved, RES0.

HPDS, bits [19:16]

From ARMv8.2:
Hierarchical permission disables bits in translation tables. Defined values are:

- **0b0000**: Disabling of hierarchical controls not supported.
- **0b0001**: Supports disabling of hierarchical controls using the TTBCR2.HPD0, TTBCR2.HPD1, and HTCR.HPD bits.
- **0b0010**: As for value **0b0001**, and adds possible hardware allocation of bits[62:59] of the translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

**ARMv8.2-AA32HPD** implements the functionality identified by the value **0b0001**.

**ARMv8.2-TTPBHA** implements the functionality added by the value **0b0010**.

---

**Note**

The value **0b0000** implies that the encoding for TTBCR2 is unallocated.

From ARMv8.1, or if ARMv8.0:
Reserved, RAZ.

Otherwise:
Reserved, RES0.

CnP, bits [15:12]

From ARMv8.2:
Common not Private translations. Defined values are:

- **0b0000**: Common not Private translations not supported.
- **0b0001**: Common not Private translations supported.

All other values are reserved.

**ARMv8.2-TTCNP** implements the functionality identified by the value **0b0001**.

From ARMv8.2 the only permitted value is **0b0001**.

From ARMv8.1, or if ARMv8.0:
Reserved, RAZ.

Otherwise:
Reserved, RES0.
XNX, bits [11:8]

From ARMv8.2:
Support for execute-never control distinction by Exception level at stage 2. Defined values are:
- 0b0000 Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
- 0b0001 Distinction between EL0 and EL1 execute-never control at stage 2 supported.
All other values are reserved.
ARMv8.2-TTS2UXN implements the functionality identified by the value 0b0001.
When ARMv8.2-TTS2UXN is implemented:
- If all of the following conditions are true it is IMPLEMENTATION DEFINED whether the value of ID_MMFR4_EL1.XNX is 0b0000 or 0b0001:
  - ID_AA64MMFR1_EL1.XNX ==1.
  - EL2 cannot use AArch32.
  - EL1 can use AArch32.
- If EL2 can use AArch32 then the only permitted value is 0b0001.
From ARMv8.1, or if ARMv8.0:
Reserved, RAZ.
Otherwise:
Reserved, RES0.

AC2, bits [7:4]
Indicates the extension of the ACTLR and HACTLR registers using ACTLR2 and HACTLR2.
Defined values are:
- 0b0000 ACTLR2 and HACTLR2 are not implemented.
- 0b0001 ACTLR2 and HACTLR2 are implemented.
All other values are reserved.
In ARMv8.0 and ARMv8.1 the permitted values are 0b0000 and 0b0001.
From ARMv8.2, the only permitted value is 0b0001.

SpecSEI, bits [3:0]
When RAS is implemented:
Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches. The defined values of this field are:
- 0b0000 The PE never generates an SError interrupt due to an External abort on a speculative read.
- 0b0001 The PE might generate an SError interrupt due to an External abort on a speculative read.
All other values are reserved.
Otherwise:
Reserved, RES0. This provides no information about whether the PE generates a speculative SError interrupt.

Accessing the ID_MMFR4_EL1
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_MMFR4_EL1</td>
<td>11</td>
<td>000</td>
<td>00</td>
<td>110</td>
<td>0010</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RO n/a EL2 RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0) && (HCR_EL2.TID3==1):
  - If the register is not RAZ/WI, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - Otherwise it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TID3==0) && (HCR_EL2.TID3==1):
  - If the register is not RAZ/WI, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - Otherwise it is implementation defined whether Non-secure EL1 read accesses to this register are trapped to EL2.
### D12.2.72 ID_PFR0_EL1, AArch32 Processor Feature Register 0

The ID_PFR0_EL1 characteristics are:

**Purpose**

Gives top-level information about the instruction sets supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register ID_PFR0_EL1[31:0] is architecturally mapped to AArch32 System register ID_PFR0[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_PFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_PFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>27</th>
<th>16</th>
<th>8</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RAS</td>
<td>DIT</td>
<td>AMU</td>
<td>RES0</td>
<td>State3</td>
<td>State2</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**RAS, bits [31:28]**

RAS Extension version.

- 0b0000  No RAS Extension.
- 0b0001  RAS Extension present.
- 0b0010  ARMv8.4-RAS present. As 0b0001, and adds support for additional ERXMISC<m>_EL1 System registers.
  Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS, and support for the optional RAS Timestamp Extension.

All other values are reserved.

From ARMv8.4, the only permitted value is 0b0010.

**ARMv8.4-RAS** implements the functionality identified by the value 0b0010.

In ARMv8.2, the only permitted value is 0b0001.

In ARMv8.1 and ARMv8.0, the permitted values are 0b0000 and 0b0001.

**DIT, bits [27:24]**

*From ARMv8.4:*

Data Independent Timing. Defined values are:

- 0b0000  AArch32 does not guarantee constant execution time of any instructions.
- 0b0001  AArch32 provides the PSTATE.DIT mechanism to guarantee constant execution time of certain instructions.
All other values are reserved.

ARMv8.4-DIT implements the functionality identified by the value 0b0001.

From ARMv8.4, the only permitted value is 0b0001.

**Otherwise:**

Reserved, RES0.

**AMU, bits [23:20]**

*From ARMv8.4:*

Activity Monitors Extension. Defined values are:
- 0b0000 Activity Monitors Extension is not implemented.
- 0b0001 Activity Monitors Extension Version 1 is implemented.

All other values are reserved.

**AMUv1** implements the functionality identified by the value 0b0001.

In ARMv8.0, ARMv8.1, ARMv8.2, and ARMv8.3, the only permitted value is 0b0000.

From ARMv8.4, the permitted values are 0b0000 and 0b0001.

**Otherwise:**

Reserved, RES0.

**Bits [19:16]**

Reserved, RES0.

**State3, bits [15:12]**

T32EE instruction set support. Defined values are:
- 0b0000 Not implemented.
- 0b0001 T32EE instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.

**State2, bits [11:8]**

Jazelle extension support. Defined values are:
- 0b0000 Not implemented.
- 0b0001 Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.
- 0b0010 Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0001.

**State1, bits [7:4]**

T32 instruction set support. Defined values are:
- 0b0000 T32 instruction set not implemented.
- 0b0001 T32 encodings before the introduction of Thumb-2 technology implemented:
  - All instructions are 16-bit.
  - A BL or BLX is a pair of 16-bit instructions.
  - 32-bit instructions other than BL and BLX cannot be encoded.
- 0b0011 T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0011.
State0, bits [3:0]

A32 instruction set support. Defined values are:

- 0b0000   A32 instruction set not implemented.
- 0b0001   A32 instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0001.

Accessing the ID_PFR0_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_PFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-    RO    n/a  RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.73 ID_PFR1_EL1, AArch32 Processor Feature Register 1

The ID_PFR1_EL1 characteristics are:

Purpose

Gives information about the AArch32 programmers' model.

Must be interpreted with ID_PFR0_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

Configurations

AArch64 System register ID_PFR1_EL1[31:0] is architecturally mapped to AArch32 System register ID_PFR1[31:0].

In an implementation that supports only AArch64 state, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ID_PFR1_EL1 is a 64-bit register.

Field descriptions

The ID_PFR1_EL1 bit assignments are:

```
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
|-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------|
| RES0              | GIC               | Virt_frac         | Sec_frac          | GenTimer          | MProgMod          | Security          |
|-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------|
| 63                | 32 31             | 28 27             | 24 23             | 20 19            | 16 15            | 12 11            |
| 8 7               | 4 3               | 0                 | Virtualization    |                  |                  |
```

Bits [63:32]

Reserved, RES0.

GIC, bits [31:28]

System register GIC CPU interface. Defined values are:

- **0b0000**: No System register interface to the GIC CPU interface is supported.
- **0b0001**: System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

Virt_frac, bits [27:24]

Virtualization fractional field. When the Virtualization field is **0b0000**, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

- **0b0000**: No features from the ARMv7 Virtualization Extensions are implemented.
- **0b0001**: The following features of the ARMv7 Virtualization Extensions are implemented:
  - The SCR.SIF bit, if EL3 is implemented.
  - The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
  - The MSR (banked register) and MRS (banked register) instructions.
  - The ERET instruction.

All other values are reserved.

In ARMv8-A the permitted values are:

- **0b0000** when EL2 is implemented.
• 0b0001 when EL2 is not implemented.
This field is only valid when the value of ID_PFR1_EL1.Virtualization is 0, otherwise it holds the value 0b0000.

_________ Note __________
The ID_ISAR registers do not identify whether the instructions added by the ARMv7 Virtualization Extensions are implemented.

Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0b0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

0b0000 No features from the ARMv7 Security Extensions are implemented.
0b0001 The following features from the ARMv7 Security Extensions are implemented:
• The VBAR register.
• The TTBCR.PD0 and TTBCR.PD1 bits.
0b0010 As for 0b0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In ARMv8-A the permitted values are:
• 0b0000 when EL3 is implemented.
• 0b0001 or 0b0010 when EL3 is not implemented.

This field is only valid when the value of ID_PFR1_EL1.Security is 0, otherwise it holds the value 0b0000.

GenTimer, bits [19:16]

Generic Timer support. Defined values are:

0b0000 Not implemented.
0b0001 Generic Timer implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0001.

Virtualization, bits [15:12]

Virtualization support. Defined values are:

0b0000 EL2, Hyp mode, and the HVC instruction not implemented.
0b0001 EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0b0001 implemented.

All other values are reserved.

In ARMv8-A the permitted values are:
• 0b0000 when EL2 is not implemented.
• 0b0001 when EL2 is implemented.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0b0001.

If EL1 cannot use AArch32 then this field has the value 0b0000.

_________ Note __________
The ID_ISARs do not identify whether the HVC instruction is implemented.
MProgMod, bits [11:8]

M profile programmers' model support. Defined values are:
- 0b0000  Not supported.
- 0b0010  Support for two-stack programmers' model.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.

Security, bits [7:4]

Security support. Defined values are:
- 0b0000  EL3, Monitor mode, and the SMC instruction not implemented.
- 0b0001  EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0b0001 implemented.
- 0b0010  As for 0b0001, and adds the ability to set the NSACR.RFR bit. Not permitted in ARMv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In ARMv8-A the permitted values are:
- 0b0000 when EL3 is not implemented.
- 0b0001 when EL3 is implemented.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0b0001.

If EL1 cannot use AArch32 then this field has the value 0b0000.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:
- 0b0000  Not supported.
- 0b0001  Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0b0001 and 0b0000.

If EL1 cannot use AArch32 then this field has the value 0b0000.

Accessing the ID_PFR1_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_PFR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>001</td>
<td>001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.74  ID_PFR2_EL1, AArch32 Processor Feature Register 2

The ID_PFR2_EL1 characteristics are:

**Purpose**

Gives information about the AArch32 programmers' model.
Must be interpreted with ID_PFR0_EL1 and ID_PFR1_EL1.
For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register ID_PFR2_EL1[31:0] is architecturally mapped to AArch32 System register ID_PFR2[31:0].
In an implementation that supports only AArch64 state, this register is UNKNOWN.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_PFR2_EL1 is a 64-bit register.

**Field descriptions**

The ID_PFR2_EL1 bit assignments are:

```
+----------------+----------------+------------------+
| 63:12          | 11:8            | 7:0              |
| Reserved, RES0 | RAS_frac         | Reserved, RES0   |
+----------------+----------------+------------------+
```

**Bits [63:12]**

Reserved, RES0.

**RAS_frac, bits [11:8]**

*When ARMv8.4-RAS is implemented:*

RAS Extension fractional field.

0b0000  If ID_PFR0_EL1.RAS == 0b0001, RAS Extension implemented.
0b0001  If ID_PFR0_EL1.RAS == 0b0001, as 0b0000 and adds support for additional ERXMISC<m> System registers.

Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS and support for the optional RAS Timestamp Extension.

All other values are reserved.

This field is valid only if ID_PFR0_EL1.RAS == 0b0001.

*Otherwise:*

Reserved, RES0.

**Bits [7:0]**

Reserved, RES0.

**Accessing the ID_PFR2_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_PFR2_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>100</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>EL1</td>
</tr>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.75  IFSR32_EL2, Instruction Fault Status Register (EL2)

The IFSR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 IFSR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**

AArch64 System register IFSR32_EL2[31:0] is architecturally mapped to AArch32 System register IFSR[31:0].

If EL1 is AArch64 only, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IFSR32_EL2 is a 64-bit register.

**Field descriptions**

The IFSR32_EL2 bit assignments are:

*When TTBCR.EAE == 0:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:17</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>16</td>
<td>FnV, bit [16]: FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.</td>
</tr>
<tr>
<td>0</td>
<td>IFAR is valid.</td>
</tr>
<tr>
<td>1</td>
<td>IFAR is not valid, and holds an UNKNOWN value.</td>
</tr>
<tr>
<td>15:13</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

This field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES0.

FS, bit [10]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00001</td>
<td>PC alignment fault.</td>
</tr>
<tr>
<td>0b00010</td>

<td>Synchronous parity or ECC error on translation table walk, level 1.</td>
</tr>
<tr>
<td>0b11110</td>
<td>Synchronous parity or ECC error on translation table walk, level 2.</td>
</tr>
</tbody>
</table>

All other values are reserved.

When the RAS Extension is implemented, 0b11001, 0b11100, and 0b11110 are reserved.

This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Using the Short-descriptor translation table formats.</td>
</tr>
<tr>
<td>0b1</td>
<td>Using the Long-descriptor translation table formats.</td>
</tr>
</tbody>
</table>

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

This field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.

FS, bits [3:0]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00001</td>
<td>PC alignment fault.</td>
</tr>
</tbody>
</table>
0b00010    Debug exception.
0b00011    Access flag fault, level 1.
0b00101    Translation fault, level 1.
0b00110    Access flag fault, level 2.
0b00111    Translation fault, level 2.
0b01000    Synchronous External abort, not on translation table walk.
0b01001    Domain fault, level 1.
0b01011    Domain fault, level 2.
0b01100    Synchronous External abort, on translation table walk, level 1.
0b01101    Permission fault, level 1.
0b01110    Synchronous External abort, on translation table walk, level 2.
0b01111    Permission fault, level 2.
0b10000    TLB conflict abort.
0b10100    IMPLEMENTATION DEFINED fault (Lockdown fault).
0b11001    Synchronous parity or ECC error on memory access, not on translation table walk.
0b11100    Synchronous parity or ECC error on translation table walk, level 1.
0b11110    Synchronous parity or ECC error on translation table walk, level 2.

All other values are reserved.
When the RAS Extension is implemented, 0b11001, 0b11100, and 0b11110 are reserved.
This field resets to an architecturally UNKNOWN value.

**When TTBCR.EAE == 1:**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:17</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>15:13</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>16</td>
<td>FnV, bit 16</td>
</tr>
</tbody>
</table>

**FnV, bit 16**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- **0**: IFAR is valid.
- **1**: IFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.
This field resets to an architecturally UNKNOWN value.

**Bits [15:13]**

Reserved, RES0.
ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

This field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0b0 Using the Short-descriptor translation table formats.

0b1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. All encodings not shown below are reserved:

0b000000 Address size fault in TTBR0 or TTBR1.

0b000001 Address size fault, level 1.

0b000010 Address size fault, level 2.

0b000011 Address size fault, level 3.

0b000101 Translation fault, level 1.

0b000110 Translation fault, level 2.

0b000111 Translation fault, level 3.

0b001001 Access flag fault, level 1.

0b001010 Access flag fault, level 2.

0b001011 Access flag fault, level 3.

0b001101 Permission fault, level 1.

0b001110 Permission fault, level 2.

0b001111 Permission fault, level 3.

0b010000 Synchronous External abort, not on translation table walk.

0b010101 Synchronous External abort, on translation table walk, level 1.

0b010110 Synchronous External abort, on translation table walk, level 2.

0b010111 Synchronous External abort, on translation table walk, level 3.

0b011000 Synchronous parity or ECC error on memory access, not on translation table walk.

0b011101 Synchronous parity or ECC error on memory access on translation table walk, level 1.

0b011110 Synchronous parity or ECC error on memory access on translation table walk, level 2.

0b011111 Synchronous parity or ECC error on memory access on translation table walk, level 3.

0b100001 PC alignment fault.

0b100010 Debug exception.

0b110000 TLB conflict abort.
All other values are reserved.

When the RAS Extension is implemented, 0b011000, 0b011101, 0b011110, and 0b011111, are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a fault at level 1.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

This field resets to an architecturally UNKNOWN value.

**Accessing the IFSR32_EL2**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFSR32_EL2</td>
<td>11</td>
<td>0101</td>
<td>100</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 - EL1 - EL2 n/a EL3 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.76 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

**Purpose**

Shows the pending status of the IRQ, FIQ, or SError interrupt.

When executing at EL2, EL3 or Secure EL1 when SCR_EL3.EEL2 == 0b0, this shows the pending status of the physical IRQ, FIQ, or SError interrupts.

When executing at either Non-secure EL1 or at Secure EL1 when SCR_EL3.EEL2 == 0b1:

- If the HCR_EL2.{IMO,FMO,AMO} bit has a value of 1, the corresponding ISR_EL1.{I,F,A} bit shows the pending status of the virtual IRQ, FIQ, or SError.
- If the HCR_EL2.{IMO,FMO,AMO} bit has a value of 0, the corresponding ISR_EL1.{I,F,A} bit shows the pending status of the physical IRQ, FIQ, or SError.

**Configurations**

AArch64 System register ISR_EL1[31:0] is architecturally mapped to AArch32 System register ISR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ISR_EL1 is a 64-bit register.

**Field descriptions**

The ISR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-9</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8</td>
<td>SError interrupt pending bit.</td>
</tr>
<tr>
<td>0b0</td>
<td>No pending SError.</td>
</tr>
<tr>
<td>0b1</td>
<td>An SError interrupt is pending.</td>
</tr>
<tr>
<td>7</td>
<td>IRQ pending bit. Indicates whether an IRQ interrupt is pending:</td>
</tr>
<tr>
<td>0b0</td>
<td>No pending IRQ.</td>
</tr>
<tr>
<td>0b1</td>
<td>An IRQ interrupt is pending.</td>
</tr>
<tr>
<td>6</td>
<td>FIQ pending bit. Indicates whether an FIQ interrupt is pending.</td>
</tr>
<tr>
<td>0b0</td>
<td>No pending FIQ.</td>
</tr>
<tr>
<td>0b1</td>
<td>An FIQ interrupt is pending.</td>
</tr>
<tr>
<td>5-0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
**Accessing the ISR_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISR_EL1</td>
<td>11</td>
<td>1100</td>
<td>000</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.77 LORC_EL1, LORegion Control (EL1)

The LORC_EL1 characteristics are:

**Purpose**

Enables and disables LORegions, and selects the current LORegion descriptor.

**Configurations**

This register is present only from ARMv8.1. Otherwise, direct accesses to LORC_EL1 are UNDEFINED.

If no LORegion descriptors are supported by the PE, then this register is RES0.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

LORC_EL1 is a 64-bit register.

**Field descriptions**

The LORC_EL1 bit assignments are:

```
+-------+-------+-------+
| 63    | 10    | 9     |
| RES0  |       | DS    |
+-------+-------+-------+

Bits [63:10]

Reserved, RES0.

DS, bits [9:2]

*From ARMv8.1:*

Descriptor Select. Selects the current LORegion descriptor accessed by LORSA_EL1, LOREA_EL1, and LORN_EL1.

The number of LORegion descriptors in IMPLEMENTATION DEFINED. The maximum number of LORegion descriptors supported is 256. If the number is less than 256, then bits[63:M+2] are RES0, where M is Log2(Number of LORegion descriptors supported by the implementation).

If this field points to an LORegion descriptor that is not supported by an implementation, then the registers LORN_EL1, LOREA_EL1, and LORSA_EL1 are RES0.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

Bit [1]

Reserved, RES0.
EN, bit [0]

*From ARMv8.1:*

Enable. Indicates whether LORegions are enabled.

- 0b0 Disabled. Memory accesses do not match any LORegions.
- 0b1 Enabled. Memory accesses may match a LORegion.

This bit is permitted to be cached in a TLB.

This field resets to 0.

*Otherwise:*

Reserved, RES0.

**Accessing the LORC_EL1**

This register can be written using MSR (register) with the following syntax:

```msr <systemreg>, <Xt>```

This register can be read using MRS with the following syntax:

```mrs <Xt>, <systemreg>```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>LORC_EL1</td>
<td>1010</td>
<td>11</td>
<td>000</td>
<td>011</td>
<td>0100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0</td>
<td>EL0: -  EL1: -  EL2: n/a  EL3: -</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && SCR_EL3.NS == 1 && SCR_EL3.TLOR == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.78 LOREA_EL1, LORegion End Address (EL1)

The LOREA_EL1 characteristics are:

**Purpose**

Holds the physical address of the end of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

**Configurations**

This register is present only from ARMv8.1. Otherwise, direct accesses to LOREA_EL1 are UNDEFINED.

This register is RES0 if any of the following apply:

- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

LOREA_EL1 is a 64-bit register.

**Field descriptions**

The LOREA_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>52-51</th>
<th>48-47</th>
<th>16-15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EA[51:48]</td>
<td>EA[47:16]</td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Bits [63:52]**

Reserved, RES0.

**EA[51:48], bits [51:48]**

*When ARMv8.2-LPA is implemented:*

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**EA[47:16], bits [47:16]**

Bits [47:16] of the end physical address of an LORegion described in the current LORegion descriptor selected by LORC_EL1.DS. Bits[15:0] of this address are defined to be 0xFFFF. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, EA[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, EA[51:48] are RES0.

This field resets to an architecturally UNKNOWN value.

**Bits [15:0]**

Reserved, RES0.
Accessing the LOREA_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOREA_EL1</td>
<td>1010</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0100</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0</td>
<td>EL0 - EL1 n/a EL2 RW EL3 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & & IsUsingAArch64(EL2) & & HCR_EL2.E2H == 0 & & HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & & IsUsingAArch64(EL2) & & HCR_EL2.E2H == 1 & & HCR_EL2.TGE == 0 & & HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) & & SCR_EL3.NS == 1 & & SCR_EL3.TLOR == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.79  LORID_EL1, LORegionID (EL1)

The LORID_EL1 characteristics are:

Purpose

Indicates the number of LORegions and LORegion descriptors supported by the PE.

Configurations

This register is present only from ARMv8.1. Otherwise, direct accesses to LORID_EL1 are UNDEFINED.

If no LORegion descriptors are implemented, then the registers LORC_EL1, LORN_EL1, LOREA_EL1, and LORSA_EL1 are RES0.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

Attributes

LORID_EL1 is a 64-bit register.

Field descriptions

The LORID_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:24]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Bits [23:16]</td>
<td>Number of LORegion descriptors supported by the PE. This is an 8-bit binary number.</td>
</tr>
<tr>
<td>Bits [15:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Bits [7:0]</td>
<td>Number of LORegions supported by the PE. This is an 8-bit binary number.</td>
</tr>
</tbody>
</table>

Note

If LORID_EL1 indicates that no LORegions are implemented, then LoadLOAcquire and StoreLORelease will behave as LoadAcquire and StoreRelease.

Accessing the LORID_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>LORID_EL1</td>
<td>1010</td>
<td>11</td>
<td>000</td>
<td>11</td>
<td>0100</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.TLOR == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.80  LORN_EL1, LORegion Number (EL1)

The LORN_EL1 characteristics are:

**Purpose**

Holds the number of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

**Configurations**

This register is present only from ARMv8.1. Otherwise, direct accesses to LORN_EL1 are UNDEFINED.

This register is RES0 if any of the following apply:

- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

LORN_EL1 is a 64-bit register.

**Field descriptions**

The LORN_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8</td>
<td>Num, bits [7:0]</td>
</tr>
<tr>
<td>7</td>
<td>Number of the LORegion</td>
</tr>
<tr>
<td>0</td>
<td>described in the current</td>
</tr>
<tr>
<td></td>
<td>LORegion descriptor selected</td>
</tr>
<tr>
<td></td>
<td>by LORC_EL1.DS.</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Bits [63:8]**

Reserved, RES0.

**Num, bits [7:0]**

Number of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS.

The maximum number of LORegions supported by the PE is 256. If the maximum number is less than 256, then bits[8:N] are RES0, where N is (Log2(Number of LORegions supported by the PE)).

If this field points to a LORegion that is not supported by the PE, then the current LORegion descriptor does not match any LORegion.

This field resets to an architecturally UNKNOWN value.

**Accessing the LORN_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th></th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;systemreg&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LORN_EL1</td>
<td>1010</td>
<td>11</td>
<td>000</td>
<td>010</td>
<td>0100</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-    -   n/a  -</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

1. If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
2. If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.
3. If IsUsingAAArch64(EL3) && SCR_EL3.NS == 1 && SCR_EL3.TLOR == 1, then accesses at EL1 or EL2 are trapped to EL3.
### D12.2.81 LORSA_EL1, LORegion Start Address (EL1)

The LORSA_EL1 characteristics are:

#### Purpose

Indicates whether the current LORegion descriptor selected by LORC_EL1.DS is enabled, and holds the physical address of the start of the LORegion.

#### Configurations

This register is present only from ARMv8.1. Otherwise, direct accesses to LORSA_EL1 are UNDEFINED.

This register is RES0 if any of the following apply:
- No LORegion descriptors are supported by the PE.
- LORC_EL1.DS points to a LORegion that is not supported by the PE.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

#### Attributes

LORSA_EL1 is a 64-bit register.

#### Field descriptions

The LORSA_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:52</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>51:48</td>
<td>SA[51:48], bits [51:48]</td>
</tr>
<tr>
<td>47:16</td>
<td>SA[47:16], bits [47:16]</td>
</tr>
<tr>
<td>15:0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Bits [63:52]**

Reserved, RES0.

**SA[51:48], bits [51:48]**

*From ARMv8.2:*

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**SA[47:16], bits [47:16]**

Bits [47:16] of the start physical address of the LORegion described in the current LORegion descriptor selected by LORC_EL1.DS. Bits[15:0] of this address are defined to be 0x0000. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, SA[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, SA[51:48] are RES0.

This field resets to an architecturally UNKNOWN value.
Bits [15:1]

Reserved, RES0.

Valid, bit [0]

Indicates whether the current LORegion Descriptor is enabled.

| 0b0 | Disabled |
| 0b1 | Enabled  |

This field resets to 0.

Accessing the LORSA_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>LORSA_EL1</td>
<td>1010 11 000 000 0100</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-   -     n/a  -</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-   RW    RW   RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-   n/a   RW   RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TLOR == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && SCR_EL3.NS == 1 && SCR_EL3.TLOR == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.2.82 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

**Purpose**

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

**Configurations**

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register PRRR[31:0] when TTBCR.EAE == 0.

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register MAIR0[31:0] when TTBCR.EAE == 1.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register NMRR[31:0] when TTBCR.EAE == 0.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register MAIR1[31:0] when TTBCR.EAE == 1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MAIR_EL1 is a 64-bit register.

**Field descriptions**

The MAIR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Attribute Number</th>
<th>Attribute Bit assignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>56 55 48 47 40 39 32 31 24 23 16 15 8 7 0</td>
</tr>
</tbody>
</table>

MAIR_EL1 is permitted to be cached in a TLB.

**Attr<n>, bits [8n+7:8n], for n = 0 to 7**

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>

<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the MAIR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL1</td>
<td>11</td>
<td>1010</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
<tr>
<td>MAIR_EL12</td>
<td>11</td>
<td>1010</td>
<td>010</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>
## Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: n/a, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
</tbody>
</table>
When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `MAIR_EL1` or `MAIR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL12</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>MAIR_EL12</td>
<td></td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 0 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0</td>
<td>-</td>
</tr>
<tr>
<td></td>
<td>&amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>MAIR_EL12</td>
<td></td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `MAIR_EL1` or `MAIR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If IsUsingAccessor(MAIR_EL1) & (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(MAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(MAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(MAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && IsUsingAccessor(MAIR_EL12) && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(MAIR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TRM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(MAIR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && IsUsingAccessor(MAIR_EL12) && HCR_EL2.TRM == 1, then write accesses at EL1 are trapped to EL2.
D12.2.83 MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL2.

Configurations

AArch64 System register MAIR_EL2[31:0] is architecturally mapped to AArch32 System register HMAIR0[31:0].

AArch64 System register MAIR_EL2[63:32] is architecturally mapped to AArch32 System register HMAIR1[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR_EL2 is a 64-bit register.

Field descriptions

The MAIR_EL2 bit assignments are:

MAIR_EL2 is permitted to be cached in a TLB.

Attr<n>, bits [8n+7:8n], for n = 0 to 7

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the MAIR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL2</td>
<td>11</td>
<td>1010</td>
<td>100</td>
<td>000</td>
<td>0010</td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>11</td>
<td>1010</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: - EL1: - EL2: n/a EL3: RW</td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: - EL1: MAIR_EL1 EL2: n/a EL3: MAIR_EL1</td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>MAIR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic MAIR_EL2 or MAIR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to MAIR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & HCR_EL2.E2H == 1 & HCR_EL2.TGE == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.84 MAIR_EL3, Memory Attribute Indirection Register (EL3)

The MAIR_EL3 characteristics are:

**Purpose**

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL3.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MAIR_EL3 is a 64-bit register.

**Field descriptions**

The MAIR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr0[7:4]</td>
<td>0b0000</td>
</tr>
<tr>
<td></td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td></td>
<td>0b00RW, RW not 0b00</td>
</tr>
<tr>
<td></td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td></td>
<td>0b01RW, RW not 0b00</td>
</tr>
<tr>
<td></td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td></td>
<td>0b10RW</td>
</tr>
<tr>
<td></td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td></td>
<td>0b11RW</td>
</tr>
<tr>
<td></td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

MAIR_EL3 is permitted to be cached in a TLB.

**Attr<n>, bits [8n+7:8n], for n = 0 to 7**

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td></td>
</tr>
<tr>
<td>Normal memory, Outer Write-Through Transient</td>
<td></td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td></td>
</tr>
<tr>
<td>Normal memory, Outer Write-Back Transient</td>
<td></td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
</tbody>
</table>
R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKOWN value.

**Accessing the MAIR_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIR_EL3</td>
<td>11</td>
<td>1010</td>
<td>110</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- - n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.85 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

AArch64 System register MIDR_EL1[31:0] is architecturally mapped to AArch32 System register MIDR[31:0].

AArch64 System register MIDR_EL1[31:0] is architecturally mapped to External register MIDR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MIDR_EL1 is a 64-bit register.

**Field descriptions**

The MIDR_EL1 bit assignments are:

```
+----------------+----------------+----------------+----------------+----------------+----------------+
| 63  | 32  | 24  | 20  | 16  | 4  | 0  |
| RES0| Implementer| Variant| PartNum| Revision| Architecture |
+----------------+----------------+----------------+----------------+----------------+----------------+
```

**Bits [63:32]**

Reserved, RES0.

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ISO8859-1 representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0</td>
<td>NUL</td>
<td>Reserved for software use</td>
</tr>

<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
</tbody>
</table>
D12 AArch64 System Register Descriptions
D12.2 General system control registers

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

- 0b0001 ARMv4.
- 0b0010 ARMv4T.
- 0b0011 ARMv5 (obsolete).
- 0b0100 ARMv5T.
- 0b0101 ARMv5TE.
- 0b0110 ARMv5TEJ.
- 0b0111 ARMv6.
- 0b1111 Architectural features are individually identified in the ID_* registers, see ID registers on page K13-7414.

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.86 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

**Purpose**
In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Configurations**
AArch64 System register MPIDR_EL1[31:0] is architecturally mapped to AArch32 System register MPIDR[31:0].
In a uniprocessor system ARM recommends that each Aff<n> field of this register returns a value of 0.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
MPIDR_EL1 is a 64-bit register.

**Field descriptions**
The MPIDR_EL1 bit assignments are:

```
| 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | Aff3 | U | RES0 | Aff2 | Aff1 | Aff0 |
| RES1 | MT |
```

**Bits [63:40]**
Reserved, RES0.

**Aff3, bits [39:32]**
Affinity level 3. See the description of Aff0 for more information.
Aff3 is not supported in AArch32 state.

**Bit [31]**
Reserved, RES1.

**U, bit [30]**
Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0b0: Processor is part of a multiprocessor system.
- 0b1: Processor is part of a uniprocessor system.

**Bits [29:25]**
Reserved, RES0.

**MT, bit [24]**
Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:

- 0b0: Performance of PEs at the lowest affinity level is largely independent.
- 0b1: Performance of PEs at the lowest affinity level is very interdependent.
Aff2, bits [23:16]
Affinity level 2. See the description of Aff0 for more information.

Aff1, bits [15:8]
Affinity level 1. See the description of Aff0 for more information.

Aff0, bits [7:0]
Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR, {Aff2, Aff1, Aff0} or MPIDR_EL1, {Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

Accessing the MPIDR_EL1
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>101</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RO, EL1: n/a, EL2: RO, EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.87 MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR1_EL1 and MVFR2_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

**Configurations**

AArch64 System register MVFR0_EL1[31:0] is architecturally mapped to AArch32 System register MVFR0[31:0].

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64 only implementation, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MVFR0_EL1 is a 64-bit register.

**Field descriptions**

The MVFR0_EL1 bit assignments are:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

- **0b0000**: Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.
- **0b0001**: All rounding modes supported.

All other values are reserved.

In ARMv8-A the permitted values are 0b0000 and 0b0001.

**FPShVec, bits [27:24]**

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

- **0b0000**: Short vectors not supported.
- **0b0001**: Short vector operation supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0b0000.
FPSqrt, bits [23:20]
Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:
- 0b0000  Not supported in hardware.
- 0b0001  Supported.
All other values are reserved.
In ARMv8-A the permitted values are 0b0000 and 0b0001.
The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]
Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:
- 0b0000  Not supported in hardware.
- 0b0001  Supported.
All other values are reserved.
In ARMv8-A the permitted values are 0b0000 and 0b0001.
The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]
Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:
- 0b0000  Not supported.
- 0b0001  Supported.
All other values are reserved.
A value of 0b0001 indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

FPDP, bits [11:8]
Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:
- 0b0000  Not supported in hardware.
- 0b0001  Supported, VFPv2.
- 0b0010  Supported, VFPv3, VFPv4, or ARMv8. VFPv3 and ARMv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.
All other values are reserved.
In ARMv8-A the permitted values are 0b0000 and 0b0010.
A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:
- VSQRT.F64 is only available if the Square root field is 0b0001.
- VDIV.F64 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.
**FPSP, bits [7:4]**

Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:

- **0b0000**: Not supported in hardware.
- **0b0001**: Supported, VFPv2.
- **0b0010**: Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the permitted values are **0b0000** and **0b0010**.

A value of **0b0001** or **0b0010** indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is **0b0001**.
- VDIV.F32 is only available if the Divide field is **0b0001**.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

**SIMDReg, bits [3:0]**

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- **0b0000**: The implementation has no Advanced SIMD and floating-point support.
- **0b0001**: The implementation includes floating-point support with 16 x 64-bit registers.
- **0b0010**: The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In ARMv8-A the permitted values are **0b0000** and **0b0010**.

**Accessing the MVFR0_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR0_EL1</td>
<td>11</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If \((\text{SCR\_EL3\_NS} = 1 \text{|| SCR\_EL3\_EEL2} = 1) \text{&& IsUsingAArch64(EL2)} \text{&& HCR\_EL2\_TID3} = 1\), then read accesses at EL1 are trapped to EL2.
D12.2.88  MVFR1_EL1, AArch32 Media and VFP Feature Register 1

The MVFR1_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0_EL1 and MVFR2_EL1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page D12-2680.

Configurations

AArch64 System register MVFR1_EL1[31:0] is architecturally mapped to AArch32 System register MVFR1[31:0].

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64 only implementation, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MVFR1_EL1 is a 64-bit register.

Field descriptions

The MVFR1_EL1 bit assignments are:

Bits [63:32]

Reserved, RES0.

SIMDFMAC, bits [31:28]

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

0b0000  Not implemented.
0b0001  Implemented.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0000 and 0b0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

FPHP, bits [27:24]

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

0b0000  Not supported.
0b0001  Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.
0b0010  As for 0b0001, and adds instructions for conversion between double-precision and half-precision.

0b0011  As for 0b0010, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In ARMv8-A the permitted values are:
- 0b0000 in an implementation without floating-point support.
- 0b0010 in an implementation with floating-point support that does not include the ARMv8.2-FP16 extension.
- 0b0011 in an implementation with floating-point support that includes the ARMv8.2-FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the SIMDHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:
- 0b0000  Not supported.
- 0b0001  SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- 0b0010  As for 0b0001, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In ARMv8-A the permitted values are:
- 0b0000 in an implementation without SIMD floating-point support.
- 0b0010 in an implementation with SIMD floating-point support that does not include the ARMv8.2-FP16 extension.
- 0b0011 in an implementation with SIMD floating-point support that includes the ARMv8.2-FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the FPHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDSP, bits [19:16]

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:
- 0b0000  Not implemented.
- 0b0001  Implemented. This value is permitted only if the SIMDInt field is 0b0001.
All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**SIMDInt, bits [15:12]**
Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:

- 0b0000 Not implemented.
- 0b0001 Implemented.

All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**SIMDLS, bits [11:8]**
Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:

- 0b0000 Not implemented.
- 0b0001 Implemented.

All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**FPDNaN, bits [7:4]**
Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:

- 0b0000 Not implemented, or hardware supports only the Default NaN mode.
- 0b0001 Hardware supports propagation of NaN values.

All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.

**FPFtZ, bits [3:0]**
Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:

- 0b0000 Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
- 0b0001 Hardware supports full denormalized number arithmetic.

All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0001.

### Accessing the MVFR1_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR1_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>001</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.89 MVFR2_EL1, AArch32 Media and VFP Feature Register 2

The MVFR2_EL1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0_EL1 and MVFR1_EL1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2680.

**Configurations**

AArch64 System register MVFR2_EL1[31:0] is architecturally mapped to AArch32 System register MVFR2[31:0].

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64 only implementation, this register is UNKNOWN.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MVFR2_EL1 is a 64-bit register.

**Field descriptions**

The MVFR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:8]</th>
<th>RES0</th>
<th>FPMisc</th>
<th>SIMDMisc</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>??</td>
<td>8</td>
<td>7</td>
</tr>
<tr>
<td>8</td>
<td>??</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>7</td>
<td></td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

**RES0**

Reserved, RES0.

**FPMisc, bits [7:4]**

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

- 0b0000 Not implemented, or no support for miscellaneous features.
- 0b0001 Support for Floating-point selection.
- 0b0010 As 0b0001, and Floating-point Conversion to Integer with Directed Rounding modes.
- 0b0011 As 0b0001, and Floating-point Round to Integer Floating-point.
- 0b0100 As 0b0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

In ARMv8-A, the permitted values are 0b0000 and 0b0100.

**SIMDMisc, bits [3:0]**

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

- 0b0000 Not implemented, or no support for miscellaneous features.
- 0b0001 Floating-point Conversion to Integer with Directed Rounding modes.
- 0b0010 As 0b0001, and Floating-point Round to Integer Floating-point.
- 0b0011 As 0b0001, and Floating-point MaxNum and MinNum.
All other values are reserved.
In ARMv8-A, the permitted values are 0b0000 and 0b0011.

Accessing the MVFR2_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR2_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>

<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TID3 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.90 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

**Purpose**

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

**Configurations**

AArch64 System register PAR_EL1[63:0] is architecturally mapped to AArch32 System register PAR[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PAR_EL1 is a 64-bit register.

**Field descriptions**

The PAR_EL1 bit assignments are:

*When PAR_EL1.F == 0b0:*

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- The PAR_EL1.{ATTR, SH} fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors.
- See the PAR_EL1.NS bit description for constraints on the value it returns.

**ATTR, bits [63:56]**

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, MAIR_EL2, and MAIR_EL3.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**Bits [55:52]**

Reserved, RES0.

**PA[51:48], bits [51:48]**

*From ARMv8.2, or if ARMv8.2-LPA is implemented:*

Extension to PA[47:12]. See PA[47:12] for more details.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PA[47:12], bits [47:12]
Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[47:12].

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, the PA[51:48] bits form the upper part of the address value. Otherwise the PA[51:48] bits are RES0.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

This field resets to an architecturally UNKNOWN value.

Bit [11]
Reserved, RES1.

IMPLEMENTATION DEFINED, bit [10]
IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

NS, bit [9]
Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, when SCR_EL3.EEL2 is 1, this bit reflects the Security state of the intermediate physical address space of the translation for the instructions:

- In AArch64 state: AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP, AT S1E0R, and AT S1E0W.
- In AArch32 state: ATS1CPR, ATS1CPW, ATS1CPRP, ATS1CPWP, ATS1CUR, and ATS1CUW.

Otherwise, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

SH, bits [8:7]
Shareability attribute, for the returned output address. Permitted values are:

- 0b00 Non-shareable.
- 0b10 Outer Shareable.
- 0b11 Inner Shareable.

The value 0b01 is reserved.

Note
This field returns the value 0b10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.
Bits [6:1]

Reserved, RES0.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

0b0 Address translation completed successfully.

This field resets to an architecturally UNKNOWN value.

When PAR_EL1.F == 0b1:

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMPLEMENTATION DEFINED, bits [63:56]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [55:52]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [51:48]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

Bits [47:12]

Reserved, RES0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

S, bit [9]

Indicates the translation stage at which the translation aborted:

0b0 Translation aborted because of a fault in the stage 1 translation.

0b1 Translation aborted because of a fault in the stage 2 translation.

This field resets to an architecturally UNKNOWN value.

PTW, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.
This field resets to an architecturally UNKNOWN value.

**Bit [7]**

Reserved, RES0.

**FST, bits [6:1]**

Fault status code, as shown in the Data Abort ESR encoding.
This field resets to an architecturally UNKNOWN value.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.
- 0b1: Address translation aborted.
This field resets to an architecturally UNKNOWN value.

**Accessing the PAR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAR_EL1</td>
<td>11</td>
<td>011</td>
<td>000</td>
<td>000</td>
<td>010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.91   REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

**Purpose**

Provides implementation-specific minor revision information.

**Configurations**

AArch64 System register REVIDR_EL1[31:0] is architecturally mapped to AArch32 System register REVIDR[31:0].

If REVIDR_EL1 has the same value as MIDR_EL1, then its contents have no significance.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

REVIDR_EL1 is a 64-bit register.

**Field descriptions**

The REVIDR_EL1 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

**Accessing the REVIDR_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>REVIDR_EL1</td>
<td>11</td>
<td>0000</td>
<td>000</td>
<td>110</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-    RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-    RO RO RO</td>

</tr>
<tr>
<td></td>
<td>-    n/a RO RO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TID1 == 1, then read accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TID1 == 1, then read accesses at EL1 are trapped to EL2.
D12.2.92   RMR_EL1, Reset Management Register (EL1)

The RMR_EL1 characteristics are:

Purpose

If EL1 is the highest implemented Exception level and this register is implemented:

• A write to the register at EL1 can request a Warm reset.
• If EL1 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Configurations

AArch64 System register RMR_EL1[31:0] is architecturally mapped to AArch32 System register RMR[31:0] when IsHighestEL(EL1).

Only implemented if EL1 is the highest implemented Exception level. In this case:

• If EL1 can use AArch32 and AArch64 then this register must be implemented.
• If EL1 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

RMR_EL1 is a 64-bit register.

Field descriptions

The RMR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-2</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>1</td>
<td>Reset Request. Setting this bit to 1 requests a Warm reset.</td>
</tr>
<tr>
<td>0</td>
<td>When EL1 can use AArch32, determines which Execution state the PE boots into after a Warm reset:</td>
</tr>
<tr>
<td></td>
<td>0b0 AArch32.</td>
</tr>
<tr>
<td></td>
<td>0b1 AArch64.</td>
</tr>
<tr>
<td></td>
<td>On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.</td>
</tr>
<tr>
<td></td>
<td>If EL1 cannot use AArch32 this bit is RAO/WI.</td>
</tr>
<tr>
<td></td>
<td>When implemented as a RW field, this field resets to 1 on a Cold reset.</td>
</tr>
</tbody>
</table>

Accessing the RMR_EL1

This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMR_EL1</td>
<td>11</td>
<td>1100</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>

<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>HighestEL(EL1)</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td></td>
<td>- RW n/a n/a</td>
</tr>
</tbody>
</table>

When RMR_EL1 is not implemented, the encoding for this register is UNDEFINED.
D12.2.93  RMR_EL2, Reset Management Register (EL2)

The RMR_EL2 characteristics are:

**Purpose**
If EL2 is the highest implemented Exception level and this register is implemented:
- A write to the register at EL2 can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**
AArch64 System register RMR_EL2[31:0] is architecturally mapped to AArch32 System register HRMR[31:0].
Only implemented if EL2 is the highest implemented Exception level. In this case:
- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.
This register has no effect if EL2 is not enabled in the current Security state.
See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**
RMR_EL2 is a 64-bit register.

**Field descriptions**
The RMR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>62</td>
<td>RR</td>
<td></td>
<td>Reset Request. Setting this bit to 1 requests a Warm reset.</td>
</tr>
<tr>
<td>61</td>
<td></td>
<td>0</td>
<td>This field resets to 0.</td>
</tr>
<tr>
<td>60</td>
<td>AA64</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Bits [63:2]**
  - Reserved, RES0.
- **RR, bit [1]**
  - Reset Request. Setting this bit to 1 requests a Warm reset.
  - This field resets to 0.
- **AA64, bit [0]**
  - When EL2 can use AArch32, determines which Execution state the PE boots into after a Warm reset:
    - 0b0  AArch32.
    - 0b1  AArch64.
  - On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.
  - If EL2 cannot use AArch32 this bit is RAO/WI.
  - When implemented as a RW field, this field resets to 1 on a Cold reset.
Accessing the RMR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMR_EL2</td>
<td>11</td>
<td>1100</td>
<td>100</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0  EL1  EL2  EL3</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; HighestEL(EL2) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; HighestEL(EL2) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When RMR_EL2 is not implemented, the encoding for this register is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.94  RMR_EL3, Reset Management Register (EL3)

The RMR_EL3 characteristics are:

**Purpose**

If EL3 is the implemented and this register is implemented:

- A write to the register at EL3 can request a Warm reset.
- If EL3 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch64 System register RMR_EL3[31:0] is architecturally mapped to AArch32 System register RMR[31:0] when IsExceptionLevelImplemented(EL3).

When EL3 is implemented:

- If EL3 can use AArch32 and AArch64 then this register must be implemented.
- If EL3 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

RMR_EL3 is a 64-bit register.

**Field descriptions**

The RMR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>2</td>
<td>Reset Request. Setting this bit to 1 requests a Warm reset. This field resets to 0.</td>
</tr>
<tr>
<td>0</td>
<td>When EL3 can use AArch32, determines which Execution state the PE boots into after a Warm reset:</td>
</tr>
<tr>
<td></td>
<td>0b0  AArch32.</td>
</tr>
<tr>
<td></td>
<td>0b1  AArch64.</td>
</tr>
</tbody>
</table>

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL3 cannot use AArch32 this bit is RAO/WI.

When implemented as a RW field, this field resets to 1 on a Cold reset.

**Accessing the RMR_EL3**

This register can be written using MSR (register) with the following syntax:
MSR `<systemreg>, <Xt>
This register can be read using MRS with the following syntax:
MRS `<Xt>, `<systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th><code>&lt;systemreg</code></th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMR_EL3</td>
<td>11</td>
<td>1100</td>
<td>110</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>HighestEL(EL3) &amp;&amp; (SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0)</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; HighestEL(EL3) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; HighestEL(EL3) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When RMR_EL3 is not implemented, the encoding for this register is UNDEFINED.
D12.2.95 RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)

The RVBAR_EL1 characteristics are:

**Purpose**

If EL1 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Configurations**

Only implemented if the highest Exception level implemented is EL1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

RVBAR_EL1 is a 64-bit register.

**Field descriptions**

The RVBAR_EL1 bit assignments are:

```
+----------+----------+
| 63       | 0        |
+----------+----------+
| Bits [63:0] | Reset Address |
+----------+----------+
```

**Accessing the RVBAR_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RVBAR_EL1</td>
<td>11</td>
<td>1100</td>
<td>000</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>

<tbody>
<tr>
<td>EL0</td>
<td>RO</td>
</tr>
<tr>
<td>EL1</td>
<td>n/a</td>
</tr>
<tr>
<td>EL2</td>
<td>n/a</td>
</tr>
<tr>
<td>EL3</td>
<td>n/a</td>
</tr>
</tbody>
</table>

When EL1 is not the highest implemented Exception level, the encoding for this register is UNDEFINED.
D12.2.96  RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Configurations

Only implemented if the highest Exception level implemented is EL2.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

The RVBAR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td>Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.</td>
</tr>
</tbody>
</table>

Accessing the RVBAR_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RVBAR_EL2</td>
<td>11</td>
<td>100</td>
<td>001</td>

<td></td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; HighestEL(EL2) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; HighestEL(EL2) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When EL2 is not the highest implemented Exception level, the encoding for this register is UNDEFINED.
**D12.2.97  RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)**

The RVBAR_EL3 characteristics are:

**Purpose**

If EL3 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Configurations**

Only implemented if the highest Exception level implemented is EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

RVBAR_EL3 is a 64-bit register.

**Field descriptions**

The RVBAR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:0]</td>
<td>Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.</td>
</tr>
</tbody>
</table>

**Accessing the RVBAR_EL3**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>RVBAR_EL3</td>
<td>11</td>
<td>110</td>
<td>110</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>HighestEL(EL3) &amp;&amp; (SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0)</td>

</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; HighestEL(EL3) &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When EL3 is not the highest implemented Exception level, the encoding for this register is UNDEFINED.
D12.2.98 S3_<op1>_Cn_Cm_<op2>, IMPLEMENTATION DEFINED registers

The S3_<op1>_Cn_Cm_<op2> characteristics are:

**Purpose**

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

S3_<op1>_Cn_Cm_<op2> is a 64-bit register.

**Field descriptions**

The S3_<op1>_Cn_Cm_<op2> bit assignments are:

```
  63 0

  IMPLEMENTATION DEFINED

  IMPLEMENTATION DEFINED, bits [63:0]

  IMPLEMENTATION DEFINED.
```
D12.2.99 SCR_EL3, Secure Configuration Register

The SCR_EL3 characteristics are:

**Purpose**

Defines the configuration of the current Security state. It specifies:

- The Security state of EL0, EL1, and EL2. The Security state is either Secure or Non-secure.
- The Execution state at lower Exception levels.
- Whether IRQ, FIQ, SError interrupts, and External abort exceptions are taken to EL3.
- Whether various operations are trapped to EL3.

**Configurations**

AArch64 System register SCR_EL3[31:0] can be mapped to AArch32 System register SCR[31:0], but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SCR_EL3 is a 64-bit register.

**Field descriptions**

The SCR_EL3 bit assignments are:

### Bits [63:22]

Reserved, RES0.

### FIEN, bit [21]

*From ARMv8.4:

Fault Injection enable.

Trap accesses to the ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1 registers from EL1 and EL2 to EL3.

Accesses to the specified registers from EL1 and EL2 generate a Trap exception to EL3.
This control does not cause any instructions to be trapped. If EL3 is not implemented, the Effective value of SCR_EL3.FIEN is 0b1. If the RAS Common Fault Injection Model Extension is not implemented, this field is RES0. This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**NMEA, bit [20]**

*When ARMv8.4-DFE is implemented:*
Non-maskable External Aborts.

When SCR_EL3.EA == 1, controls whether PSTATE.A masks SError interrupts at EL3.

- 0b0 If SCR_EL3.EA == 1, asserted SError interrupts are not taken at EL3 if PSTATE.A == 1.
- 0b1 If SCR_EL3.EA == 1, asserted SError interrupts are taken at EL3 regardless of the value of PSTATE.A.

When SCR_EL3.EA == 0, asserted SError interrupts are not taken at EL3 regardless of the value of PSTATE.A and this bit.

This field resets to 0.

**Otherwise:**
Reserved, RES0.

**EASE, bit [19]**

*When ARMv8.4-DFE is implemented:*
External aborts to SError interrupt vector.

- 0b0 Synchronous External abort exceptions taken to EL3 are taken to the appropriate synchronous exception vector offset from VBAR_EL3.
- 0b1 Synchronous External abort exceptions taken to EL3 are taken to the appropriate SError interrupt vector offset from VBAR_EL3.

This field resets to 0.

**Otherwise:**
Reserved, RES0.

**EEL2, bit [18]**

*When ARMv8.4-SecEL2 is implemented:*
Secure EL2 Enable.

- 0b0 All behaviors associated with Secure EL2 are disabled. All registers, including timer registers, defined by ARMv8.4-SecEL2 are UNDEFINED, and those timers are disabled.
- 0b1 All behaviors associated with Secure EL2 are enabled.

When the value of this bit is 1, then:
- When SCR_EL3.NS == 0, the SCR_EL3.RW bit is treated as 1 for all purposes other than reading or writing the register.
- If Secure EL1 is using AArch32, then any of the following operations, executed in Secure EL1, is trapped to Secure EL2 using the EC value of ESR_EL2.EC==0x3:
  - A read or write of the SCR.
  - A read or write of the NSACR.
  - A read or write of the SDCR.
  - A read or write of the MVBAR.
  - Execution of an ATS12NSO** instruction.
• If Secure EL1 is using AArch32, then any of the following operations, executed in Secure EL1, is trapped to Secure EL2 using the EC value of ESR_EL2.EC == 0x0:
  — Execution of an SRS instruction that uses R13_mon.
  — Execution of an MRS (Banked register) or MSR (Banked register) instruction that would access SPSR_mon, R13_mon, or R14_mon.

Note

If the Effective value of SCR_EL3.EEL2 is 0, then these operations executed in Secure EL1 using AArch32 are trapped to EL3.

In a Secure only implementation that does not implement EL3 but implements EL2, behaves as if SCR_EL3.EEL2 == 1.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

API, bit [17]

From ARMv8.4, when ARMv8.3-PAuth is implemented:

Controls the use of instructions related to Pointer Authentication:

• PACGA, XPACD, XPAC1, and XPACLRI.
• AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZ, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETTA, ERETB, LDRAA and LDRAB when:
  — In EL0, when HCR_EL2.TGE==0 or HCR_EL2.E2H==0, and the associated SCTLR_EL1.En<N><M> == 1.
  — In EL0, when HCR_EL2.TGE==1 and HCR_EL2.E2H==1, and the associated SCTLR_EL2.En<N><M> == 1.
  — In EL1, when the associated SCTLR_EL1.En<N><M> == 1.
  — In EL2, when the associated SCTLR_EL2.En<N><M> == 1.

0b0 The use of any instruction related to pointer authentication in any Exception level except EL3 when the instructions are enabled are trapped to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.API bit.

0b1 This control does not cause any instructions to be trapped.

Note

If ARMv8.3-PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

This field resets to an architecturally UNKNOWN value.

From ARMv8.3, when ARMv8.3-PAuth is implemented:

Controls the use of instructions related to Pointer Authentication:

• PACGA, XPACD, XPAC1, and XPACLRI.
• AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB, PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZ, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETTA, ERETB, LDRAA and LDRAB when:
  — In Non-secure EL0, when HCR_EL2.TGE==0 or HCR_EL2.E2H==0, and the associated SCTLR_EL1.En<N><M> == 1.
— In Non-secure EL0, when HCR_EL2.TGE==1 and HCR_EL2.E2H==1, and the associated SCTLR_EL2.En<N><M> == 1.
— In Secure EL0, when the associated SCTLR_EL2.En<N><M> == 1.
— In Secure or Non-secure EL1, when the associated SCTLR_EL1.En<N><M> == 1.
— In EL2, when the associated SCTLR_EL2.En<N><M> == 1.

\(0b0\) The use of any instruction related to pointer authentication in any Exception level except EL3 when the instructions are enabled are trapped to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.API bit.

\(0b1\) This control does not cause any instructions to be trapped.

**Note**

If ARMv8.3-PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### APK, bit [16]

**When ARMv8.3-PAuth is implemented:**

Trap registers holding "key" values for Pointer Authentication. Traps accesses to the following registers from EL1 or EL2 to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.APK bit or other traps:

- APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1, APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APGAKeyLo_EL1, and APGAKeyHi_EL1.

\(0b0\) Access to the registers holding "key" values for pointer authentication from EL1 or EL2 are trapped to EL3 unless they are trapped to EL2 as a result of the HCR_EL2.APK bit or other traps.

\(0b1\) This control does not cause any instructions to be trapped.

**Note**

If ARMv8.3-PAuth is implemented but EL3 is not implemented, the system behaves as if this bit is 1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### TERR, bit [15]

**When RAS is implemented:**

Trap Error record accesses. Trap accesses to the following registers from EL1 and EL2 to EL3:

EL1 using AArch64: ERRIDR_EL1, ERRSELR_EL1, ERXADDR_EL1, ERXCTRLR_EL1, ERXFR_EL1, ERXMISC0_EL1, ERXMISC1_EL1, and ERXSTATUS_EL1. When ARMv8.4-RAS is implemented, ERXMISC2_EL1, and ERXMISC3_EL1.

EL1 using AArch32: ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTRLR, ERXCTRLR2, ERXFR, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS. When ARMv8.4-RAS is implemented, ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

\(0b0\) This control does not cause any instructions to be trapped.

\(0b1\) Accesses to the specified registers from EL1 and EL2 generate a Trap exception to EL3.

This field resets to an architecturally UNKNOWN value.
**TLOR, bit [14]**

*When ARMv8.1-LOR is implemented:*

Trap LOR registers. Traps accesses to the LORSA_EL1, LOREA_EL1, LORN_EL1, LORC_EL1, and LORID_EL1 registers from EL1 and EL2 to EL3, unless the access has been trapped to EL2.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** EL1 and EL2 accesses to the LOR registers that are not UNDEFINED are trapped to EL3, unless it is trapped HCR_EL2.TLOR.

This field resets to an architecturally **UNKNOWN** value.

**TWI, bit [12]**

Traps EL2, EL1, and EL0 execution of WFI instructions to EL3, from both Security states and both Execution states.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by Sctlr.nTWI, HCR.TWIE, Sctlr_EL1.nTWI, Sctlr_EL2.nTWI, or HCR_EL2.TWIE.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

**Note**

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

This field resets to an architecturally **UNKNOWN** value.
ST, bit [11]

Traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3, from AArch64 state only.

0b0  Secure EL1 using AArch64 accesses to the CNTPS_TVAL_EL1, CNTPS_CTL_EL1, and CNTPS_CVAL_EL1 are trapped to EL3 when Secure EL2 is disabled. If Secure EL2 is enabled, the behavior is as if the value of this field was 0b1.

0b1  This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

RW, bit [10]

Execution state control for lower Exception levels.

0b0  Lower levels are all AArch32.

0b1  The next lower level is AArch64.

If EL2 is present:

• EL2 is AArch64.
• EL2 controls EL1 and EL0 behaviors.

If EL2 is not present:

• EL1 is AArch64.
• EL0 is determined by the Execution state described in the current process state when executing at EL0.

If all lower Exception levels cannot use AArch32, then this bit is RAO/WI.

When SCR_EL3.{EEL2, NS} == {1, 0}, this bit is treated as 1 for all purposes other than reading or writing the register.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

SIF, bit [9]

From ARMv8.4:

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from memory marked in the first stage of translation as being Non-secure. The possible values for this bit are:

0b0  Secure state instruction fetches from memory marked in the first stage of translation as being Non-secure are permitted.

0b1  Secure state instruction fetches from memory marked in the first stage of translation as being Non-secure are not permitted.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

From ARMv8.3, or if ARMv8.2, or ARMv8.1 or ARMv8.0:

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory.

0b0  Secure state instruction fetches from Non-secure memory are permitted.

0b1  Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HCE, bit [8]
Hypervisor Call instruction enable. Enables HVC instructions at EL3 and, if EL2 is enabled in the current Security state, at EL2 and EL1, in both Execution states.
0b0 HVC instructions are UNDEFINED.
0b1 HVC instructions are enabled at EL3, EL2, and EL1.

--- Note  
HVC instructions are always UNDEFINED at EL0 and, if Secure EL2 is disabled, at Secure EL1.

---
If EL2 is not implemented, this bit is RES0.
This field resets to an architecturally UNKNOWN value.

SMD, bit [7]
Secure Monitor Call disable. Disables SMC instructions at EL1 and above, from both Security states and both Execution states.
0b0 SMC instructions are enabled at EL1 and above.
0b1 SMC instructions are UNDEFINED at EL1 and above.

--- Note  
SMC instructions are always UNDEFINED at EL0.

---
This field resets to an architecturally UNKNOWN value.

Bit [6]
Reserved, RES0.

Bits [5:4]
Reserved, RES1.

EA, bit [3]
External Abort and SError interrupt routing.
0b0 When executing at Exception levels below EL3, External aborts and SError interrupts are not taken to EL3.
In addition, when executing at EL3:
• SError interrupts are not taken.
• External aborts are taken to EL3.
0b1 When executing at any Exception level, External aborts and SError interrupts are taken to EL3.
For more information, see Asynchronous exception routing on page D1-2199.
This field resets to an architecturally UNKNOWN value.

FIQ, bit [2]
Physical FIQ Routing.
0b0 When executing at Exception levels below EL3, physical FIQ interrupts are not taken to EL3.
When executing at EL3, physical FIQ interrupts are not taken.
0b1 When executing at any Exception level, physical FIQ interrupts are taken to EL3.
For more information, see Asynchronous exception routing on page D1-2199.
This field resets to an architecturally UNKNOWN value.
IRQ, bit [1]  
Physical IRQ Routing.  
0b0 When executing at Exception levels below EL3, physical IRQ interrupts are not taken to EL3.  
When executing at EL3, physical IRQ interrupts are not taken.  
0b1 When executing at any Exception level, physical IRQ interrupts are taken to EL3.  
For more information, see Asynchronous exception routing on page D1-2199.  
This field resets to an architecturally UNKNOWN value.  

NS, bit [0]  
Non-secure bit.  
0b0 Indicates that EL0 and EL1 are in Secure state.  
0b1 Indicates that Exception levels lower than EL3 are in Non-secure state, and so memory accesses from those Exception levels cannot access Secure memory.  
When SCR_EL3.{EEL2, NS} == {1, 0}, then EL2 is using AArch64 and in Secure state.  
This field resets to an architecturally UNKNOWN value.

Accessing the SCR_EL3  
This register can be written using MSR (register) with the following syntax:  
MSR <systemreg>, <Xt>  
This register can be read using MRS with the following syntax:  
MRS <Xt>, <systemreg>  
This syntax is encoded with the following settings in the instruction encoding:  

Accessibility  
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.100  SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL1 and EL0.

**Configurations**

AArch64 System register SCTLR_EL1[31:0] is architecturally mapped to AArch32 System register SCTLR[31:0].

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL1 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SCTLR_EL1 is a 64-bit register.

**Field descriptions**

The SCTLR_EL1 bit assignments are:

- **Bits [63:32]**
  - Reserved, RES0.
- **EnIA, bit [31]**
  - From ARMv8.3:
    - Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL1&0 translation regime.
    - Possible values of this bit are:
      - 0b0  Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.
      - 0b1  Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.
**Note**

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**EnIB, bit [30]**

*From ARMv8.3:*

Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

Possible values of this bit are:

- **0b0**: Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
- **0b1**: Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

**Note**

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**LSMAOE, bit [29]**

*When ARMv8.2-LSMAOC is implemented:*

Load Multiple and Store Multiple Atomicity and Ordering Enable.

- **0b0**: For all memory accesses at EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- **0b1**: The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL0 is as defined for ARMv8.0.

This bit is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES1.
nTLSMD, bit [28]

When ARMv8.2-LSMAOC is implemented:

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

0b0 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.

0b1 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

EnDA, bit [27]

From ARMv8.3:

Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

Possible values of this bit are:

0b0 Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.

0b1 Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.

Note

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions to EL1, from AArch64 state only. This applies to DC CVAU, DC CIVAC, DC CVAC, DC CVAP, and IC IVAU.

0b0 Execution of the specified instructions at EL0 using AArch64 is trapped to EL1.

0b1 This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1,1}, this bit has no effect on execution at EL0.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate by VA to the Point of Unification instruction can be trapped when the value of this control is 1.
In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

**EE, bit [25]**

Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

The possible values of this bit are:

0b0  Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

0b1  Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is **RES0**.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is **RES1**.

The EE bit is permitted to be cached in a TLB.

When **ARMv8.1-VHE** is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an **IMPLEMENTATION DEFINED** value.

**E0E, bit [24]**

Endianness of data accesses at EL0.

The possible values of this bit are:

0b0  Explicit data accesses at EL0 are little-endian.

0b1  Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is **RES0**. This option is not permitted when SCTLR_EL1.EE is **RES1**.

If an implementation only supports Big-endian accesses at EL0 then this bit is **RES1**. This option is not permitted when SCTLR_EL1.EE is **RES0**.

This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR, and STTRH instructions executed at EL1.

When **ARMv8.1-VHE** is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

**SPAN, bit [23]**

*From ARMv8.1:*

Set Privileged Access Never, on taking an exception to EL1.

0b0  PSTATE.PAN is set to 1 on taking an exception to EL1.

0b1  The value of PSTATE.PAN is left unchanged on taking an exception to EL1.

When **ARMv8.1-VHE** is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, **RES1**.

**Bit [22]**

Reserved, **RES1**.
IESB, bit [21]

When ARMv8.2-IESB is implemented:

Implicit error synchronization event enable. Possible values are:

0b0       Disabled.
0b1       An implicit error synchronization event is added:
          • After each exception taken to EL1.
          • Before the operational pseudocode of each ERET instruction executed at EL1.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL1 and before each DRPS instruction executed at EL1, in addition to the other cases where it is added.

This field is part of ARMv8.2-IESB.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [20]

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0       This control has no effect on memory access permissions.
0b1       Any region that is writable in the EL1&0 translation regime is forced to XN for accesses from software executing at EL1 or EL0.

The WXN bit is permitted to be cached in a TLB.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

nTWE, bit [18]

When HCR_EL2.TGE == 1 and (SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1):

Traps EL0 execution of WFE instructions to EL2, from both Execution states.

0b0       Any attempt to execute a WFE instruction at EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1       This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.
Otherwise:

Traps EL0 execution of WFE instructions to EL1, from both Execution states.

0b0  Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

When HCR_EL2.TGE == 1 and (SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1):

Traps EL0 execution of WFI instructions to EL2, from both Execution states.

0b0  Any attempt to execute a WFI instruction at EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

Otherwise:

Traps EL0 execution of WFI instructions to EL1, from both Execution states.

0b0  Any attempt to execute a WFI instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.
When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**UCT, bit [15]**

Traps EL0 accesses to the CTR_EL0 to EL1, from AArch64 state only.

- **0b0** Accesses to the CTR_EL0 from EL0 using AArch64 are trapped to EL1.
- **0b1** This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**DZE, bit [14]**

Traps EL0 execution of DC ZVA instructions to EL1, from AArch64 state only.

- **0b0** Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped to EL1. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions this trap applies to are not supported.
- **0b1** This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**EnDB, bit [13]**

*From ARMv8.3:*

Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL1&0 translation regime.

- **0b0** Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
- **0b1** Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

___ Note ___

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

___

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**I, bit [12]**

Instruction access Cacheability control, for accesses at EL0 and EL1:

- **0b0** All instruction access to Normal memory from EL0 and EL1 are Non-cacheable for all levels of instruction and unified cache.
  
  If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

- **0b1** This control has no effect on the Cacheability of instruction access to Normal memory from EL0 and EL1.
  
  If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.
When the value of the HCR_EL2.DC bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the SCTLR_EL1.I bit.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to 0.

Bit [11]
Reserved, RES1.

Bit [10]
Reserved, RES0.

UMA, bit [9]
User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, from AArch64 state only.
0b0 Any attempt at EL0 using AArch64 to execute an MSR, MSR(register), or MSR(immediate) instruction that accesses the DAIIF is trapped to EL1.
0b1 This control does not cause any instructions to be trapped.
When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.
In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

SED, bit [8]
SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.
0b0 SETEND instruction execution is enabled at EL0 using AArch32.
0b1 SETEND instructions are UNDEFINED at EL0 using AArch32.
If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.
If EL0 cannot use AArch32, this bit is RES1.
When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.
In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

ITD, bit [7]
IT Disable. Disables some uses of IT instructions at EL0 using AArch32.
0b0 All IT instruction functionality is enabled at EL0 using AArch32.
0b1 Any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED:
• All encodings of the IT instruction with hw1[3:0]!=1000.
• All encodings of the subsequent instruction with the following values for hw1:
  — 0b11xxxxxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
  — 0b1001xxxxxxx: ADD Rd, PC, #imm
  — 0b1000xxxxxxx: ADD Rd, [PC, #imm]
  — 0b0101xxxxxxx: ADD Rd, [PC, #imm]
  — 0b01001xxxxxxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
  — 0b010001xxxxxxx: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.
These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.
It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-3540

If EL0 cannot use AArch32, this bit is RES1.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

nAA, bit [6]

When ARMv8.4-LSE is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL1 and EL0 under certain conditions.

- 0b0: LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRLH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.
- 0b1: This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRLH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from EL0:

- 0b0: EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
- 0b1: EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

If EL0 cannot use AArch32, this bit is RES0.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.
SA0, bit [4]
SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2164.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.E2H, TGE is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

SA, bit [3]
SP Alignment check enable. When set to 1, if a load or store instruction executed at EL1 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2164.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.E2H, TGE is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

C, bit [2]
Cacheability control, for data accesses.

0b0 All data access to Normal memory from EL0 and EL1, and all Normal memory accesses to the EL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.

0b1 This control has no effect on the Cacheability of:
• Data access to Normal memory from EL0 and EL1.
• Normal memory accesses to the EL1&0 stage 1 translation tables.

When the value of the HCR_EL2.DC bit is 1, the PE ignores SCLTR.C. This means that Non-secure EL0 and Non-secure EL1 data accesses to Normal memory are Cacheable.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.E2H, TGE is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to 0.

A, bit [1]
Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0.

0b0 Alignment fault checking disabled when executing at EL1 or EL0.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1 Alignment fault checking enabled when executing at EL1 or EL0.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.E2H, TGE is {1, 1}, this bit has no effect on execution at EL0.

In a system where the PE resets into EL1, this field resets to an architecturally UNKNOWN value.

M, bit [0]
MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0b0 EL1 and EL0 stage 1 address translation disabled.
See the SCTLR_EL1.I field for the behavior of instruction accesses to Normal memory.

0b1 EL1 and EL0 stage 1 address translation enabled.
If the value of HCR_EL2.{DC, TGE} is not {0, 0} then in Non-secure state the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of the field.

When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this bit has no effect on the PE.

In a system where the PE resets into EL1, this field resets to 0.

### Accessing the SCTLR_EL1

This register can be written using MSR (register) with the following syntax:

\[
\text{MSR } <\text{systemreg}>, <\text{Xt}>
\]

This register can be read using MRS with the following syntax:

\[
\text{MRS } <\text{Xt}>, <\text{systemreg}>
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL1</td>
<td>11</td>
<td>0001</td>
<td>000</td>
<td>000</td>
<td>000</td>
</tr>
<tr>
<td>SCTLR_EL12</td>
<td>11</td>
<td>0001</td>
<td>101</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
When \texttt{HCR\_EL2.E2H} is 1, without explicit synchronization, access from EL3 using the mnemonic \texttt{SCTLR\_EL1} or \texttt{SCTLR\_EL12} are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If IsUsingAccessor(SCTLR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at
  EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) &&
  IsUsingAccessor(SCTLR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then read accesses at
  EL1 are trapped to EL2.

— If IsUsingAccessor(SCTLR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at
  EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) &&
  IsUsingAccessor(SCTLR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at
  EL1 are trapped to EL2.

— If IsUsingAccessor(SCTLR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM
  == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) &&
  IsUsingAccessor(SCTLR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TVM
  == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) &&
  IsUsingAccessor(SCTLR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TVM
  == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) &&
  IsUsingAccessor(SCTLR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
  IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TVM
  == 1, then accesses at EL1 are trapped to EL2.
D12.2.101  SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL2. When ARMv8.1-VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, these controls apply also to execution at EL0.

**Configurations**

AArch64 System register SCTLR_EL2[31:0] is architecturally mapped to AArch32 System register HSCTLR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SCTLR_EL2 is a 64-bit register.

**Field descriptions**

The SCTLR_EL2 bit assignments are:

*When HCR_EL2.E2H != 0b1 or HCR_EL2.TGE != 0b1:*

This format applies in all ARMv8.0 implementations, and from ARMv8.1 when the *Effective value of HCR_EL2.{E2H, TGE} != \{1, 1\}.*

**Bits [63:32]**

Reserved, RES0.

**EnIA, bit [31]**

*From ARMv8.3:*

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
Possible values of this bit are:

0b0  Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.
0b1  Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

--- Note ---
This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

--- In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value. ---

Otherwise:
Reserved, RES0.

EnIB, bit [30]

From ARMv8.3:
Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
Possible values of this bit are:

0b0  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
0b1  Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

--- Note ---
This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

--- In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value. ---

Otherwise:
Reserved, RES0.

Bits [29:28]
Reserved, RES1.

EnDA, bit [27]

From ARMv8.3:
Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
Possible values of this bit are:

0b0  Pointer authentication (using the APDAKey_EL1 key) of instruction addresses is not enabled.
0b1  Pointer authentication (using the APDAKey_EL1 key) of instruction addresses is enabled.
Note
This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [26]
Reserved, RES0.

EE, bit [25]
Endianness of data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL1&0 translation regime.
The possible values of this bit are:

0b0 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are little-endian.

0b1 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.
If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.
The EE bit is permitted to be cached in a TLB.
In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]
Reserved, RES0.

Bits [23:22]
Reserved, RES1.

IESB, bit [21]
When ARMv8.2-IESB is implemented:
Implicit Error Synchronization event Enable.

0b0 Disabled.

0b1 An implicit error synchronization event is added:
• After each exception taken to EL2.
• Before the operational pseudocode of each ERET instruction executed at EL2.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL2 and before each DRPS instruction executed at EL2, in addition to the other cases where it is added.
This field is part of ARMv8.2-IESB.
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can force all memory regions that are writable to be treated as XN:

0b0 This control has no effect on memory access permissions.
0b1 Any region that is writable in the EL2 or EL2&0 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:14]

Reserved, RES0.

EnDB, bit [13]

*From ARMv8.3:*

Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

Possible values of this bit are:

0b0 Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
0b1 Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

--- Note ---

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

---

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

0b0 All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 or EL2&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1 This control has no effect on the Cacheability of instruction access to Normal memory from EL2.
If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 or EL2&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

**Bit [11]**

Reserved, RES1.

**Bits [10:7]**

Reserved, RES0.

**nAA, bit [6]**

*When ARMv8.4-LSE is implemented:*

Non-aligned access. This bit controls generation of Alignment faults at EL2 under certain conditions.

- **0b0** LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLUR, STLURH, STLR, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.

- **0b1** This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLR, STLRH, STLUR, STLURH, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [5:4]**

Reserved, RES1.

**SA, bit [3]**

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see *SP alignment checking on page D1-2164*.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**C, bit [2]**

Cacheability control, for data accesses.

- **0b0** All data access to Normal memory from EL2, and all Normal memory accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.

- **0b1** This control has no effect on the Cacheability of:
  - Data access to Normal memory from EL2.
  - Normal memory accesses to the EL2 translation tables.

This bit has no effect on the EL1&0 or EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

- **0b0** Alignment fault checking disabled when executing at EL2.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1  Alignment fault checking enabled when executing at EL2.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0b0  EL2 stage 1 address translation disabled.
See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.

0b1  EL2 stage 1 address translation enabled.

In a system where the PE resets into EL2, this field resets to 0.

When HCR_EL2.E2H == 0b1 and HCR_EL2.TGE == 0b1:

This format applies only from ARMv8.1 when EL2 is enabled in the current Security state and HCR_EL2.{E2H, TGE} == {1, 1}.

Bits [63:32]

Reserved, RES0.

EnIA, bit [31]

From ARMv8.3:

Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
Possible values of this bit are:

0b0  Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is not enabled.
Pointer authentication (using the APIAKey_EL1 key) of instruction addresses is enabled.

--- Note ---
This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

---
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

EnIB, bit [30]

*From ARMv8.3:*
Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.
Possible values of this bit are:

- **0b0** Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
- **0b1** Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

--- Note ---
This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

---
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

LSMAOE, bit [29]

*When ARMv8.2-LSMAOC is implemented:*
Load Multiple and Store Multiple Atomicity and Ordering Enable.

- **0b0** For all memory accesses at EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- **0b1** The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL0 is as defined for ARMv8.0.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES1.
nTLSMD, bit [28]

When ARMv8.2-LSMAOC is implemented:

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

0b0 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.

0b1 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

EnDA, bit [27]

From ARMv8.3:

Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

0b0 Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.

0b1 Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.

Note

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions to EL2, from AArch64 state only. This applies to DC CVAU, DC CIVAC, DC CVAC, DC CVAP, and IC IVAU.

0b0 Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped to EL2.

0b1 This control does not cause any instructions to be trapped.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

EE, bit [25]

Endianness of data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime.
The possible values of this bit are:

0b0  Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime are little-endian.

0b1  Explicit data accesses at EL2, stage 1 translation table walks in the EL2 or EL2&0 translation regime, and stage 2 translation table walks in the EL2&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.

E0E, bit [24]

Endianness of data accesses at EL0.

0b0  Explicit data accesses at EL0 are little-endian.

0b1  Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0. This option is not permitted when SCTLR_EL1.EE is RES1.

If an implementation only supports Big-endian accesses at EL0 then this bit is RES1. This option is not permitted when SCTLR_EL1.EE is RES0.

This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR, and STTRH instructions executed at EL1.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

SPAN, bit [23]

Set Privileged Access Never, on taking an exception to EL2.

0b0  PSTATE.PAN is set to 1 on taking an exception to EL2.

0b1  The value of PSTATE.PAN is left unchanged on taking an exception to EL2.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Bit [22]

Reserved, RES1.

IESB, bit [21]

When ARMv8.2-IESB is implemented:

Implicit Error Synchronization event Enable.

0b0  Disabled.

0b1  An implicit error synchronization event is added:

•  After each exception taken to EL2.

•  Before the operational pseudocode of each ERET instruction executed at EL2.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL2 and before each DRPS instruction executed at EL2, in addition to the other cases where it is added.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
Bit [20]

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.
0b1  Any region that is writable in the EL2 or EL2&0 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to EL2, from both Execution states.

0b0  Any attempt to execute a WFE instruction at EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

——— Note ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

———

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to EL2, from both Execution states.

0b0  Any attempt to execute a WFI instruction at EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1  This control does not cause any instructions to be trapped.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

——— Note ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

———

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

UCT, bit [15]

Traps EL0 accesses to the CTR_EL0 to EL2, from AArch64 state only.

0b0  Accesses to the CTR_EL0 from EL0 using AArch64 are trapped to EL2.
0b1  This control does not cause any instructions to be trapped.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.
DZE, bit [14]

Traps EL0 execution of DC ZVA instructions to EL2, from AArch64 state only.

- **0b0**: Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped to EL2. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions that this trap applies to are not supported.
- **0b1**: This control does not cause any instructions to be trapped.

In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.

EnDB, bit [13]

*From ARMv8.3:*

Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL2&0 translation regime.

Possible values of this bit are:

- **0b0**: Pointer authentication (using the APDBKey_EL1 key) of instruction addresses is not enabled.
- **0b1**: Pointer authentication (using the APDBKey_EL1 key) of instruction addresses is enabled.

--- **Note** ---

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

--- **Note** ---

In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, **RES0**.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2 and EL0:

- **0b0**: All instruction access to Normal memory from EL2 and EL0 are Non-cacheable for all levels of instruction and unified cache.
  - If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
- **0b1**: This control has no effect on the Cacheability of instruction access to Normal memory from EL2 and EL0.
  - If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

Bit [11]

Reserved, **RES1**.

Bits [10:9]

Reserved, **RES0**.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.

- **0b0**: SETEND instruction execution is enabled at EL0 using AArch32.
- **0b1**: SETEND instructions are **UNDEFINED** at EL0 using AArch32.
If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.
If EL0 cannot use AArch32, this bit is RES1.
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**ITD, bit [7]**

IT Disable. Disables some uses of IT instructions at EL0 using AArch32.

0b0 All IT instruction functionality is enabled at EL0 using AArch32.

0b1 Any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED:
- All encodings of the IT instruction with hw1[3:0]=1000.
- All encodings of the subsequent instruction with the following values for hw1:
  - 0b11xxxxxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
  - 0b1011xxxxxxxxxxxx: All instructions in 'Miscellaneous 16-bit instructions' in the ARMv8 ARM, section F3.2.5.
  - 0b10100xxxxxxxxxxx: ADD Rd, PC, #imm
  - 0b01001xxxxxxxxxxx: LDR Rd, [PC, #imm]
  - 0b010001xx1xxxx111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:
- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-3540.

If EL0 cannot use AArch32, this bit is RES1.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**nAA, bit [6]**

*When ARMv8.4-LSE is implemented:*

Non-aligned access. This bit controls generation of Alignment faults at EL2 and EL0 under certain conditions.

0b0 LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDAHR, LDLAR, LDLARH, STLAR, STLLAR, STLR, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.

0b1 This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDAHR, LDLAR, LDLARH, STLAR, STLLAR, STLR, STLRH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**CP15BEN, bit [5]**

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from EL0:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB</td>
</tr>
<tr>
<td></td>
<td>instructions is UNDEFINED.</td>
</tr>
<tr>
<td>0b1</td>
<td>EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB</td>
</tr>
<tr>
<td></td>
<td>instructions is enabled.</td>
</tr>
</tbody>
</table>

If EL0 cannot use AArch32, this bit is RES0.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAO/WI.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**SA0, bit [4]**

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-2164](#).

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**SA, bit [3]**

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-2164](#).

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**C, bit [2]**

Cacheability control, for data accesses.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>All data access to Normal memory from EL2 and EL0, and all Normal memory</td>
</tr>
<tr>
<td></td>
<td>accesses to the EL2&amp;0 translation tables, are Non-cacheable for all levels</td>
</tr>
<tr>
<td></td>
<td>of data and unified cache.</td>
</tr>
<tr>
<td>0b1</td>
<td>This control has no effect on the Cacheability of:</td>
</tr>
<tr>
<td></td>
<td>• Data access to Normal memory from EL2 and EL0.</td>
</tr>
<tr>
<td></td>
<td>• Normal memory accesses to the EL2&amp;0 translation tables.</td>
</tr>
</tbody>
</table>

This bit has no effect on the EL3 translation regimes.

In a system where the PE resets into EL2, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL2 and EL0.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Alignment fault checking disabled when executing at EL2 and EL0. Instructions</td>
</tr>
<tr>
<td></td>
<td>that load or store one or more registers, other than load/store exclusive and</td>
</tr>
<tr>
<td></td>
<td>load-acquire/store-release, do not check that the address being accessed is</td>
</tr>
<tr>
<td></td>
<td>aligned to the size of the data element(s) being accessed.</td>
</tr>
</tbody>
</table>
| 0b1     | Alignment fault checking enabled when executing at EL2 and EL0. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception. Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.
## M, bit [0]

MMU enable for EL2&0 stage 1 address translation. Possible values of this bit are:

- **0b0**: EL2&0 stage 1 address translation disabled.
  - See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.
- **0b1**: EL2&0 stage 1 address translation enabled.
  - In a system where the PE resets into EL2, this field resets to 0.

### Accessing the SCTLR_EL2

This register can be written using MSR (register) with the following syntax:

\[
\text{MSR <systemreg>, Xt}
\]

This register can be read using MRS with the following syntax:

\[
\text{MRS Xt, <systemreg>}
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL2</td>
<td>11</td>
<td>0001</td>
<td>100</td>
<td>000</td>
<td>0000</td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>11</td>
<td>0001</td>
<td>000</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>

</tbody>
</table>

When \( HCR \_EL2.E2H \) is 1, without explicit synchronization, access from EL2 using the mnemonic SCTLR_EL2 or SCTLR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to SCTLR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If $(\text{SCR\_EL3.NS} == 1 \lor \text{SCR\_EL3.EEL2} == 1) \land \text{IsUsingAArch64(EL2)} \land \text{IsUsingAccessor(SCTLR\_EL2)} \land \text{HCR\_EL2.E2H} == 0 \land \text{HCR\_EL2.NV} == 1$, then accesses at EL1 are trapped to EL2.

- If $(\text{SCR\_EL3.NS} == 1 \lor \text{SCR\_EL3.EEL2} == 1) \land \text{IsUsingAArch64(EL2)} \land \text{IsUsingAccessor(SCTLR\_EL2)} \land \text{HCR\_EL2.E2H} == 1 \land \text{HCR\_EL2.TGE} == 0 \land \text{HCR\_EL2.NV} == 1$, then accesses at EL1 are trapped to EL2.
D12.2.102  SCTLR_EL3, System Control Register (EL3)

The SCTLR_EL3 characteristics are:

**Purpose**
Provides top level control of the system, including its memory system, at EL3.

**Configurations**
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL3 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
SCTLR_EL3 is a 64-bit register.

**Field descriptions**
The SCTLR_EL3 bit assignments are:

![Bit assignments diagram]

**Bits [63:32]**
Reserved, RES0.

**EnIA, bit [31]**
Controls enabling of pointer authentication (using the APIAKey_EL1 key) of instruction addresses in the EL3 translation regime.
Possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Pointer authentication is not enabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>Pointer authentication is enabled.</td>
</tr>
</tbody>
</table>

**Note**
This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. Specifically, when the field is 1, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.
EnIB, bit [30]

From ARMv8.3:
Controls enabling of pointer authentication (using the APIBKey_EL1 key) of instruction addresses in the EL3 translation regime.
Possible values of this bit are:
0b0 Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is not enabled.
0b1 Pointer authentication (using the APIBKey_EL1 key) of instruction addresses is enabled.

Note
This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. Specifically, when the field is 1, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [29:28]
Reserved, RES1.

EnDA, bit [27]

From ARMv8.3:
Controls enabling of pointer authentication (using the APDAKey_EL1 key) of instruction addresses in the EL3 translation regime.
0b0 Pointer authentication (using the APDAKey_EL1 key) of data addresses is not enabled.
0b1 Pointer authentication (using the APDAKey_EL1 key) of data addresses is enabled.

Note
This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. Specifically, when the field is 1, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [26]
Reserved, RES0.

EE, bit [25]
Endianness of data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime.
The possible values of this bit are:
0b0 Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are little-endian.
Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

In a system where the PE resets into EL3, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

IESB, bit [21]

From ARMv8.2:

Implicit error synchronization event enable. Possible values are:

- **0b0** Disabled.
- **0b1** An implicit error synchronization event is added:
  - After each exception taken to EL3.
  - Before the operational pseudocode of each ERET instruction executed at EL3.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL3 and before each DRPS instruction executed at EL3, in addition to the other cases where it is added.

This field is part of .

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL3 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- **0b0** This control has no effect on memory access permissions.
- **0b1** Any region that is writable in the EL3 translation regime is forced to XN for accesses from software executing at EL3.

The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.
Bits [15:14]

Reserved, RES0.

EnDB, bit [13]

From ARMv8.3:
Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL3 translation regime.

0b0  Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.
0b1  Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

Note
This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL3:

0b0  All instruction access to Normal memory from EL3 are Non-cacheable for all levels of instruction and unified cache.
      If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1  This control has no effect on the Cacheability of instruction access to Normal memory from EL3.
      If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.

In a system where the PE resets into EL3, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:7]

Reserved, RES0.

nAA, bit [6]

When ARMv8.4-LSE is implemented:
Non-aligned access. This bit controls generation of Alignment faults at EL3 under certain conditions.

0b0  LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLUR, STLURH, STLR, STLRH, STLLRH, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.
0b1  This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.
This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [5:4]**

Reserved, RES1.

**SA, bit [3]**

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL3 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see SP alignment checking on page D1-2164.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**C, bit [2]**

Cacheability control, for data accesses.

- **0b0**  All data access to Normal memory from EL3, and all Normal memory accesses to the EL3 translation tables, are Non-cacheable for all levels of data and unified cache.
- **0b1**  This control has no effect on the Cacheability of:
  - Data access to Normal memory from EL3.
  - Normal memory accesses to the EL3 translation tables.

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.

In a system where the PE resets into EL3, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL3.

- **0b0**  Alignment fault checking disabled when executing at EL3. Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
- **0b1**  Alignment fault checking enabled when executing at EL3. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception. Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

**M, bit [0]**

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

- **0b0**  EL3 stage 1 address translation disabled. See the SCTLR_EL3.1 field for the behavior of instruction accesses to Normal memory.
- **0b1**  EL3 stage 1 address translation enabled.

In a system where the PE resets into EL3, this field resets to 0.

**Accessing the SCTLR_EL3**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTRL_EL3</td>
<td>11</td>
<td>001</td>
<td>110</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-    -    n/a   RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.103  TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

The control register for stage 1 of the EL1&0 translation regime.

Configurations

AArch64 System register TCR_EL1[31:0] is architecturally mapped to AArch32 System register TTBCR[31:0].

AArch64 System register TCR_EL1[63:32] is architecturally mapped to AArch32 System register TTBCR2[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions

The TCR_EL1 bit assignments are:

Any of the bits in TCR_EL1, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

Bits [63:55]

Reserved, RES0.

NFD1, bit [54]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR1_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR1_EL1.

If SVE is implemented, the affected access types include:

• All accesses due to an SVE non-fault contiguous load instruction.
• Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
• Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See The Scalable Vector Extension (SVE) on page A1-75 for more information.

Defined values are:

0b0  Does not disable stage 1 translation table walks using TTBR1_EL1.
0b1  A TLB miss on a virtual address that is translated using TTBR1_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

NFD0, bit [53]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR0_EL1.

If SVE is implemented, the affected access types include:

• All accesses due to an SVE non-fault contiguous load instruction.
• Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
• Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See The Scalable Vector Extension (SVE) on page A1-75 for more information.

Defined values are:

0b0  Does not disable stage 1 translation table walks using TTBR0_EL1.
0b1  A TLB miss on a virtual address that is translated using TTBR0_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TBID1, bit [52]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

0b0  TCR_EL1.TBI1 applies to Instruction and Data accesses.
0b1  TCR_EL1.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
TBID0, bit [51]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

- \(0b0\) TCR_EL1.TBID0 applies to Instruction and Data accesses.
- \(0b1\) TCR_EL1.TBID0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL1.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

- \(0b0\) For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- \(0b1\) For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

Otherwise:

Reserved, RES0.

HWU161, bit [49]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

- \(0b0\) For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- \(0b1\) For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

Otherwise:

Reserved, RES0.

HWU160, bit [48]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

- \(0b0\) For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- \(0b1\) For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

Otherwise:

Reserved, RES0.
Otherwise:
Reserved, RES0.

HWU159, bit [47]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

0b0 For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU062, bit [46]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU061, bit [45]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
HWU060, bit [44]

When ARMv8.2-TTPBHA is implemented:

- **Hardware Use.** Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.
  - 0b0: For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
  - 0b1: For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The *Effective value* of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:

- Reserved, RES0.

HWU059, bit [43]

When ARMv8.2-TTPBHA is implemented:

- **Hardware Use.** Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.
  - 0b0: For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
  - 0b1: For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The *Effective value* of this field is 0 if the value of TCR_EL1.HPD0 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:

- Reserved, RES0.

HPD1, bit [42]

When ARMv8.1-HPD is implemented:

- **Hierarchical Permission Disables.** This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL1.
  - 0b0: Hierarchical permissions are enabled.
  - 0b1: Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:

- Reserved, RES0.

HPD0, bit [41]

When ARMv8.1-HPD is implemented:

- **Hierarchical Permission Disables.** This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL1.
  - 0b0: Hierarchical permissions are enabled.
  - 0b1: Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:

- Reserved, RES0.
HD, bit [40]

When ARMv8.1-TTHM is implemented:

- Hardware management of dirty state in stage 1 translations from EL0 and EL1.
  - 0b0: Stage 1 hardware management of dirty state disabled.
  - 0b1: Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

Otherwise:

Reserved, RES0.

HA, bit [39]

When ARMv8.1-TTHM is implemented:

- Hardware Access flag update in stage 1 translations from EL0 and EL1.
  - 0b0: Stage 1 Access flag update disabled.
  - 0b1: Stage 1 Access flag update enabled.

Otherwise:

Reserved, RES0.

TBI1, bit [38]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses. Defined values are:

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL1.TBID1 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:
- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

TBI0, bit [37]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses. Defined values are:

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.
Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

**AS, bit [36]**

ASID Size. Defined values are:

- 0b0: 8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
- 0b1: 16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

**Bit [35]**

Reserved, RES0.

**IPS, bits [34:32]**

Intermediate Physical Address Size.

- 0b000: 32 bits, 4GB.
- 0b001: 36 bits, 64GB.
- 0b010: 40 bits, 1TB.
- 0b011: 42 bits, 4TB.
- 0b100: 44 bits, 16TB.
- 0b101: 48 bits, 256TB.
- 0b110: 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL1 are 0b0000.

This field resets to an architecturally UNKNOWN value.

**TG1, bits [31:30]**

Granule size for the TTBR1_EL1.

- 0b01: 16KB.
- 0b10: 4KB.
- 0b11: 64KB.

Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

### SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1_EL1.

- **0b00**: Non-shareable.
- **0b10**: Outer Shareable.
- **0b11**: Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

This field resets to an architecturally UNKNOWN value.

### ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

- **0b00**: Normal memory, Outer Non-cacheable.
- **0b01**: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10**: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11**: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

### IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

- **0b00**: Normal memory, Inner Non-cacheable.
- **0b01**: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10**: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11**: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

### EPD1, bit [23]

Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL1. The encoding of this bit is:

- **0b0**: Perform translation table walks using TTBR1_EL1.
- **0b1**: A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

### A1, bit [22]

Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:

- **0b0**: TTBR0_EL1.ASID defines the ASID.
- **0b1**: TTBR1_EL1.ASID defines the ASID.

This field resets to an architecturally UNKNOWN value.
T1SZ, bits [21:16]
The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{(64-T1SZ)}$ bytes.
The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.
This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]
Granule size for the TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Granule Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>4KB</td>
</tr>
<tr>
<td>0b01</td>
<td>64KB</td>
</tr>
<tr>
<td>0b10</td>
<td>16KB</td>
</tr>
</tbody>
</table>

Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.
It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.
This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Shareability Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>0b10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>0b11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.
This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Cacheability Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Cacheability Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Inner Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
EPD0, bit [7]

Translation table walk disable for translations using TTBR0_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL1. The encoding of this bit is:

- 0b0 Perform translation table walks using TTBR0_EL1.
- 0b1 A TLB miss on an address that is translated using TTBR0_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL1. The region size is $2^{(64-T0SZ)}$ bytes. The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Accessing the TCR_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCR_EL1</td>
<td>11</td>
<td>0010</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
<tr>
<td>TCR_EL12</td>
<td>11</td>
<td>0010</td>
<td>101</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
<td>RW</td>
<td>n/a</td>
<td>RW</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
<td>HCR_EL2.NV1 == 0</td>
<td></td>
<td>HCR_EL2.NV2 == 0) &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>[VNCR_EL2.BADDR &lt;&lt; 12 + 0x120]</td>
<td>RW</td>
</tr>
</tbody>
</table>
When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `TCR_EL1` or `TCR_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

1. If `IsUsingAccessor(TCR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1`, then read accesses at EL1 are trapped to EL2.

2. If `HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0` &&
   `IsUsingAccessor(TCR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1`, then read accesses at EL1 are trapped to EL2.

3. If `IsUsingAccessor(TCR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.

4. If `HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0` &&
   `IsUsingAccessor(TCR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.

5. If `IsUsingAccessor(TCR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TRVM == 1`, then read accesses at EL1 are trapped to EL2.

6. If `HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0` &&
   `IsUsingAccessor(TCR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TVM == 1`, then read accesses at EL1 are trapped to EL2.

7. If `IsUsingAccessor(TCR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.

8. If `HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0` &&
   `IsUsingAccessor(TCR_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1`, then write accesses at EL1 are trapped to EL2.

9. If `IsUsingAccessor(TCR_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) &&
   IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1`, then accesses at EL1 are trapped to EL2.
D12.2.104 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

**Purpose**

The control register for stage 1 of the EL2, or EL2&0, translation regime:

- When the *Effective value* of HCR_EL2.E2H is 0, this register controls stage 1 of the EL2 translation regime, that supports a single VA range, translated using TTBR0_EL2.
- When the value of HCR_EL2.E2H is 1, this register controls stage 1 of the EL2&0 translation regime, that supports both:
  - A lower VA range, translated using TTBR0_EL2.
  - A higher VA range, translated using TTBR1_EL2.

**Configurations**

AArch64 System register TCR_EL2[31:0] is architecturally mapped to AArch32 System register HTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TCR_EL2 is a 64-bit register.

**Field descriptions**

The TCR_EL2 bit assignments are:

*When HCR_EL2.E2H == 0:*

Any of the bits in TCR_EL2, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.
Bit [30]
Reserved, RES0.

TBID, bit [29]

*When ARMv8.3-PAuth is implemented:*

Controls the use of the top byte of instruction addresses for address matching.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>TCR_EL2.TBI applies to Instruction and Data accesses.</td>
</tr>
<tr>
<td>0b1</td>
<td>TCR_EL2.TBI applies to Data accesses only.</td>
</tr>
</tbody>
</table>

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

*Otherwise:*
Reserved, RES0.

HWU62, bit [28]

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.</td>
</tr>
</tbody>
</table>

The *Effective value* of this field is 0 if the value of TCR_EL2.HPD is 0.

*Otherwise:*
Reserved, RES0.

HWU61, bit [27]

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.</td>
</tr>
</tbody>
</table>

The *Effective value* of this field is 0 if the value of TCR_EL2.HPD is 0.

*Otherwise:*
Reserved, RES0.

HWU60, bit [26]

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.</td>
</tr>
</tbody>
</table>

The *Effective value* of this field is 0 if the value of TCR_EL2.HPD is 0.

*Otherwise:*
Reserved, RES0.
**HWU59, bit [25]**

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.</td>
</tr>
</tbody>
</table>

The *Effective value* of this field is 0 if the value of TCR_EL2.HPD is 0. This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**HPD, bit [24]**

*When ARMv8.1-HPD is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Hierarchical permissions are enabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>Hierarchical permissions are disabled.</td>
</tr>
</tbody>
</table>

*Note*

In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero. This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Bit [23]**

Reserved, RES1.

**HD, bit [22]**

*When ARMv8.1-TTHM is implemented:*

Hardware management of dirty state in stage 1 translations from EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Stage 1 hardware management of dirty state disabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**HA, bit [21]**

*When ARMv8.1-TTHM is implemented:*

Hardware Access flag update in stage 1 translations from EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Stage 1 Access flag update disabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>Stage 1 Access flag update enabled.</td>
</tr>
</tbody>
</table>
This field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES0.

**TBI, bit [20]**

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

0b0  Top Byte used in the address calculation.
0b1  Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TBID is 1, then this field only applies to Data accesses.

If the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

This field resets to an architecturally **UNKNOWN** value.

**Bit [19]**

Reserved, RES0.

**PS, bits [18:16]**

Physical Address Size.

0b000  32 bits, 4GB.
0b001  36 bits, 64GB.
0b010  40 bits, 1TB.
0b011  42 bits, 4TB.
0b100  44 bits, 16TB.
0b101  48 bits, 256TB.
0b110  52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b110 or 0b111 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are 0b0000.

This field resets to an architecturally **UNKNOWN** value.

**TG0, bits [15:14]**

Granule size for the TTBR0_EL2.

0b00  4KB.
0b01  64KB.
0b10  16KB.
Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

**SH0, bits [13:12]**
Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Non-shareable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Outer Shareable.</td>
</tr>
<tr>
<td>0b11</td>
<td>Inner Shareable.</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7231.

This field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Inner Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Bits [7:6]**
Reserved, RES0.

**T0SZ, bits [5:0]**
The size offset of the memory region addressed by TTBR0_EL2. The region size is $2^{(64-T0SZ)}$ bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.
**When HCR_EL2.E2H == 1:**

This view of the register is only valid from ARMv8.1 when HCR_EL2.E2H is 1.

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

**Bits [63:55]**

Reserved, RES0.

**NFD1, bit [54]**

*When SVE is implemented:*

Non-fault translation table walk disable for stage 1 translations using TTBR1_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR1_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See *The Scalable Vector Extension (SVE)* on page A1-75 for more information.

Defined values are:

\[0b0\] Does not disable stage 1 translation table walks using TTBR1_EL2.

\[0b1\] A TLB miss on a virtual address that is translated using TTBR1_EL2 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
NFD0, bit [53]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR0_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See The Scalable Vector Extension (SVE) on page A1-75 for more information.

Defined values are:

- 0b0 Does not disable stage 1 translation table walks using TTBR0_EL2.
- 0b1 A TLB miss on a virtual address that is translated using TTBR0_EL2 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID1, bit [52]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

- 0b0 TCR_EL2.TBI1 applies to Instruction and Data accesses.
- 0b1 TCR_EL2.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID0, bit [51]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

- 0b0 TCR_EL2.TBIO applies to Instruction and Data accesses.
- 0b1 TCR_EL2.TBIO applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

- 0b0 For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU161, bit [49]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

0b0 For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU160, bit [48]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

0b0 For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU159, bit [47]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

0b0 For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
HWU062, bit [46]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- **0b0** For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0. This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- **0b0** For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0. This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU060, bit [44]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- **0b0** For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0. This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

- **0b0** For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 For translations using `TTBR0_EL1`, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The **Effective value** of this field is 0 if the value of TCR_EL2.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HPD1, bit [42]**

*When ARMv8.1-HPD is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by `TTBR1_EL2`.

0b0 Hierarchical permissions are enabled.

0b1 Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HPD0, bit [41]**

*When ARMv8.1-HPD is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by `TTBR0_EL2`.

0b0 Hierarchical permissions are enabled.

0b1 Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HD, bit [40]**

*When ARMv8.1-TTHM is implemented:*

Hardware management of dirty state in stage 1 translations from EL2.

0b0 Stage 1 hardware management of dirty state disabled.

0b1 Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HA, bit [39]**

*When ARMv8.1-TTHM is implemented:*

Hardware Access flag update in stage 1 translations from EL2.

0b0 Stage 1 Access flag update disabled.

0b1 Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
TB11, bit [38]

From ARMv8.1:

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR1_EL2 region, or ignored and used for tagged addresses. Defined values are:

0b0  Top Byte used in the address calculation.
0b1  Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TB1D1 is 1, then this field only applies to Data accesses.

If the value of TB11 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

•  A branch or procedure return within EL0 or EL1.
•  An exception taken to EL1.
•  An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TB10, bit [37]

When ARMv8.1-VHE is implemented:

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses. Defined values are:

0b0  Top Byte used in the address calculation.
0b1  Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TB1D0 is 1, then this field only applies to Data accesses.

If the value of TB10 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

•  A branch or procedure return within EL0 or EL1.
•  An exception taken to EL1.
•  An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AS, bit [36]

ASID Size. Defined values are:

0b0  8 bit - the upper 8 bits of TTBR0_EL2 and TTBR1_EL2 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
0b1  16 bit - the upper 16 bits of TTBR0_EL2 and TTBR1_EL2 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.
Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

- 0b000: 32 bits, 4GB.
- 0b001: 36 bits, 64GB.
- 0b010: 40 bits, 1TB.
- 0b011: 42 bits, 4TB.
- 0b100: 44 bits, 16TB.
- 0b101: 48 bits, 256TB.
- 0b110: When ARMv8.2-LPA is implemented, 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b010 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granularity size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

TG1, bits [31:30]

From ARMv8.1:

Granule size for the TTBR1_EL2.

- 0b01: 16KB.
- 0b10: 4KB.
- 0b11: 64KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH1, bits [29:28]

From ARMv8.1:

Shareability attribute for memory associated with translation table walks using TTBR1_EL2.

Defined values are:

- 0b00: Non-shareable.
- 0b10: Outer Shareable.
- 0b11: Inner Shareable.
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**ORGN1, bits [27:26]**

*From ARMv8.1:*
Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**IRGN1, bits [25:24]**

*From ARMv8.1:*
Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Normal memory, Inner Non-cacheable.</td>
</tr>
<tr>
<td>0b01</td>
<td>Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b10</td>
<td>Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>0b11</td>
<td>Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**EPD1, bit [23]**

*From ARMv8.1:*
Translation table walk disable for translations using TTBR1_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL2. The encoding of this bit is:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Perform translation table walks using TTBR1_EL2.</td>
</tr>
<tr>
<td>0b1</td>
<td>A TLB miss on an address that is translated using TTBR1_EL2 generates a Translation fault. No translation table walk is performed.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**A1, bit [22]**
Selects whether TTBR0_EL2 or TTBR1_EL2 defines the ASID. The encoding of this bit is:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>TTBR0_EL2.ASID defines the ASID.</td>
</tr>
<tr>
<td>0b1</td>
<td>TTBR1_EL2.ASID defines the ASID.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
T1SZ, bits [21:16]

From ARMv8.1:

The size offset of the memory region addressed by TTBR1_EL2. The region size is 2^{64-T1SZ} bytes.
The maximum and minimum possible values for T1SZ depend on the level of translation table and
the memory translation granule size, as described in the AArch64 Virtual Memory System
Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TG0, bits [15:14]

From ARMv8.1:

Granule size for the TTBR0_EL2.

0b00  4KB.
0b01  64KB.
0b10  16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then
the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED
choice of the sizes that has been implemented for all purposes other than the value read back from
this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value
that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH0, bits [13:12]

From ARMv8.1:

Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00  Non-shareable.
0b10  Outer Shareable.
0b11  Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior
is CONstrained UNPredictable, as described in Reserved values in System and memory-mapped
registers and translation table entries on page K1-7231.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ORGN0, bits [11:10]

From ARMv8.1:

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00  Normal memory, Outer Non-cacheable.
0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.
Reserved, RES0.

IRGN0, bits [9:8]

From ARMv8.1:
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.
- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Reserved, RES0.

EPD0, bit [7]

From ARMv8.1:
Translation table walk disable for translations using TTBR0_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL2. The encoding of this bit is:
- 0b0: Perform translation table walks using TTBR0_EL2.
- 0b1: A TLB miss on an address that is translated using TTBR0_EL2 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Reserved, RES0.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

From ARMv8.1:
The size offset of the memory region addressed by TTBR0_EL2. The region size is 2^(64-T0SZ) bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Reserved, RES0.

Accessing the TCR_EL2

This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>010</td>
<td>0000</td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>11</td>
<td>0010</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCR_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0   EL1   EL2   EL3</td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-   TCR_EL1 n/a   TCR_EL1</td>
</tr>
<tr>
<td></td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TCR_EL2 or TCR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to TCR_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 && SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && IsUsingAccessor(TCR_EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 && SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && IsUsingAccessor(TCR_EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.105 TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

**Purpose**

The control register for stage 1 of the EL3 translation regime.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TCR_EL3 is a 64-bit register.

**Field descriptions**

The TCR_EL3 bit assignments are:

Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

**Bits [63:32]**

- Reserved, RES0.

**Bit [31]**

- Reserved, RES1.

**Bit [30]**

- Reserved, RES0.

**TBID, bit [29]**

*When ARMv8.3-PAuth is implemented:*

- Controls the use of the top byte of instruction addresses for address matching.
  - 0b0 TCR_EL3.TBI applies to Instruction and Data accesses.
  - 0b1 TCR_EL3.TBI applies to Data accesses only.

  This affects addresses where the address would be translated by tables pointed to by TTBR0_EL3.

**Otherwise:**

- Reserved, RES0.
HWU62, bit [28]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

0b0  Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

0b0  Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU60, bit [26]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

0b0  Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

0b0  Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.
HPD, bit [24]

*When ARMv8.1-HPD is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL3.

- 0b0: Hierarchical permissions are enabled.
- 0b1: Hierarchical permissions are disabled.

---

**Note**

In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

---

Bit [23]

Reserved, RES0.

HD, bit [22]

*When ARMv8.1-TTHM is implemented:*

Hardware management of dirty state in stage 1 translations from EL3.

- 0b0: Stage 1 hardware management of dirty state disabled.
- 0b1: Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

---

HA, bit [21]

*When ARMv8.1-TTHM is implemented:*

Hardware Access flag update in stage 1 translations from EL3.

- 0b0: Stage 1 Access flag update disabled.
- 0b1: Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

---

TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL3 region, or ignored and used for tagged addresses.

- 0b0: Top Byte used in the address calculation.
- 0b1: Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL3. It has an effect whether the EL3 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL3.TBID is 1, then this field only applies to Data accesses.
Otherwise, if the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL3.
- A exception taken to EL3.
- An exception return to EL3.

This field resets to an architecturally unknown value.

**Bit [19]**

Reserved, RES0.

**PS, bits [18:16]**

Physical Address Size.

- 0b000 32 bits, 4GB.
- 0b001 36 bits, 64GB.
- 0b010 40 bits, 1TB.
- 0b011 42 bits, 4TB.
- 0b100 44 bits, 16TB.
- 0b101 48 bits, 256TB.
- 0b110 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL3 are 0b0000.

This field resets to an architecturally unknown value.

**TG0, bits [15:14]**

Granule size for the TTBR0_EL3.

- 0b00 4KB.
- 0b01 64KB.
- 0b10 16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an implementation defined choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is implementation defined whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally unknown value.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using TTBR0_EL3.

- 0b00 Non-shareable.
- 0b10 Outer Shareable.
- 0b11 Inner Shareable.
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is constrained unpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

This field resets to an architecturally unknown value.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally unknown value.

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally unknown value.

**Bits [7:6]**

Reserved, RES0.

**T0SZ, bits [5:0]**

The size offset of the memory region addressed by TTBR0_EL3. The region size is \(2^{(64-T0SZ)}\) bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally unknown value.

### Accessing the TCR_EL3

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCR_EL3</td>
<td>11</td>
<td>0010</td>
<td>110</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td></td>
<td>- - n/a RW</td>

<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.106  TPIDR_EL0, EL0 Read/Write Software Thread ID Register

The TPIDR_EL0 characteristics are:

**Purpose**

Provides a location where software executing at EL0 can store thread identifying information, for
OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch64 System register TPIDR_EL0[31:0] is architecturally mapped to AArch32 System register
TPIDRURW[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TPIDR_EL0 is a 64-bit register.

**Field descriptions**

The TPIDR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:0]</td>
<td>Thread ID. Thread identifying information stored by software running at this Exception level. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the TPIDR_EL0**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>

<td></td>
</tr>
</tbody>
</table>
D12.2.107 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

**Purpose**

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch64 System register TPIDR_EL1[31:0] is architecturally mapped to AArch32 System register TPIDRPRW[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TPIDR_EL1 is a 64-bit register.

**Field descriptions**

The TPIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>Thread ID. Thread identifying information stored by software running at this Exception level. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the TPIDR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>

</tbody>
</table>
D12.2.108  TPIDR_EL2, EL2 Software Thread ID Register

The TPIDR_EL2 characteristics are:

**Purpose**

Provides a location where software executing at EL2 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch64 System register TPIDR_EL2[31:0] is architecturally mapped to AArch32 System register HTPIDR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TPIDR_EL2 is a 64-bit register.

**Field descriptions**

The TPIDR_EL2 bit assignments are:

![chart]

**Bits [63:0]**

Thread ID. Thread identifying information stored by software running at this Exception level. This field resets to an architecturally UNKNOWN value.

**Accessing the TPIDR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TPIDR_EL2</td>
<td>11</td>
<td>1101</td>
<td>100</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; SCR_EL3.NS == 1 &amp;&amp; SCR_EL3.EEL2 == 1 &amp;&amp; SCR_EL3.EEL2 == 1</td>
<td>-     [VNCR_EL2.BADDR &lt;&lt; 12 + 0x90]</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; SCR_EL3.NS == 1 &amp;&amp; SCR_EL3.EEL2 == 1</td>
<td>-     n/a    RW   RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.109  TPIDR_EL3, EL3 Software Thread ID Register

The TPIDR_EL3 characteristics are:

**Purpose**
Provides a location where software executing at EL3 can store thread identifying information, for OS management purposes.
The PE makes no use of this register.

**Configurations**
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
TPIDR_EL3 is a 64-bit register.

**Field descriptions**
The TPIDR_EL3 bit assignments are:

```
+-----------------+-----------------+
| Bits [63:0]     | Thread ID       |
+-----------------+-----------------+
| 63              | Thread ID       |
| 0               | Thread ID       |
```

**Accessing the TPIDR_EL3**
This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

```
<systemreg>  op0  CRn  op1  op2  CRm
TPIDR_EL3    11  1101  110  010  0000
```

**Accessibility**
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.110  TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes. The PE makes no use of this register.

**Configurations**

AArch64 System register TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 System register TPIDRRO[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TPIDRRO_EL0 is a 64-bit register.

**Field descriptions**

The TPIDRRO_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Thread ID</th>

</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>RO RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
## TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

### Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL1&0 translation regime, and other information for this translation regime.

### Configurations

AArch64 System register TTBR0_EL1[63:0] is architecturally mapped to AArch32 System register TTBR0[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

TTBR0_EL1 is a 64-bit register.

### Field descriptions

The TTBR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID, bits [63:48]</td>
<td>An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID. If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Note**

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL1.IPS is 0b110, then:

- Register bits[47:z] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.

- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
• Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.
• In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

--- Note ---

• In an implementation that includes ARMv8.2-LPA a TCR_EL1.IPS value of 0b110, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.
• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL1.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not 0b110 then:

• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

--- Note ---

This definition applies:

• To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
• To any implementation that does not include ARMv8.2-LPA.

If any TTBR0_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1.

0b0 The translation table entries pointed to by TTBR0_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR0_EL1 for other PEs in the Inner Shareable domain. This is not affected by:

• The value of TTBR0_EL1.CnP on those other PEs.
• The value of the current ASID.
• If EL2 is enabled in the current Security state, the value of the current VMID.

0b1 The translation table entries pointed to by TTBR0_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1 and all of the following apply:

• The translation table entries are pointed to by TTBR0_EL1.
• The translation tables relate to the same translation regime.
• The ASID is the same as the current ASID.
• If EL2 is enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR0_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONstrained UNPREDICTABLE, see CONstrained UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

When **HCR_EL2.E2H** is 1, without explicit synchronization, access from EL3 using the mnemonic TTBR0_EL1 or TTBR0_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If IsUsingAccessor(TTBR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(TTBR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(TTBR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(TTBR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If IsUsingAccessor(TTBR0_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccessor(TTBR0_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.
D12.2.112   TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

**Purpose**

When \( \text{HCR\_EL2.E2H} \) is 0, holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

When \( \text{HCR\_EL2.E2H} \) is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL2&0 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register TTBR0_EL2[47:1] is architecturally mapped to AArch32 System register HTTBR[47:1].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR0_EL2 is a 64-bit register.

**Field descriptions**

The TTBR0_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>BADDR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

*From ARMv8.1:*

When \( \text{HCR\_EL2.E2H} \) is 0, this field is \text{RES0}.

When \( \text{HCR\_EL2.E2H} \) is 1, it holds an ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are \text{RES0}.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**BADDR, bits [47:1]**

Translation table base address, \( A[47:x] \) or \( A[51:x], \) bits[47:1].

--- **Note** ---

- Translation table base addresses of 52 bits, \( A[51:x] \), are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.
In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL2.{I}PS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where x is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

In an implementation that includes ARMv8.2-LPA:

- A TCR_EL2.{I}PS value of 0b110, that selects an OA size of 52 bits, is permitted only when using the 64KB translation granule.
- The OA size is specified by:
  - The value of TCR_EL2.PS when the value of HCR_EL2.E2H is 0.
  - The value of TCR_EL2.IPS when the value of HCR_EL2.E2H is 1.

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL2.{I}PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

Note

If any TTBR0_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T0SZ, the stage of translation, and the translation granule size. This field resets to an architecturally UNKNOWN value.
CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1.

0b0 The translation table entries pointed to by TTBR0_EL2 for the current translation regime, and ASID if applicable, are permitted to differ from corresponding entries for TTBR0_EL2 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0_EL2.CnP on those other PEs.
- When the current translation regime is the EL2&0 regime, the value of the current ASID.

0b1 The translation table entries pointed to by TTBR0_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR0_EL2.
- The translation tables relate to the same translation regime.
- If that translation regime is the EL2&0 regime, the ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

Note

If the value of the TTBR0_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL2s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTBR0_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>000</td>
<td>0000</td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>11</td>
<td>0010</td>
<td>000</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>TTBR0_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>TTBR0_EL2</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR0_EL2</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR0_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR0_EL2 or TTBR0_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an _EL1 accessor is used, refer to TTBR0_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see "Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.113 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL3 translation regime, and other information for this translation regime.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR0_EL3 is a 64-bit register.

**Field descriptions**

The TTBR0_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:48]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

---

**Note**

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL3.PS is 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTBNP bit[0] of the stage 1 translation table base address is zero.
In an implementation that includes ARMv8.2-LPA a TCR_EL3.PS value of 0b110, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL3.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL3.PS is not 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR0_EL3[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL3, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL3.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

**When ARMv8.2-TTCNP is implemented:**

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL3 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1.

0b0 The translation table entries pointed to by TTBR0_EL3, for the current translation regime, are permitted to differ from corresponding entries for TTBR0_EL3 for other PEs in the Inner Shareable domain. This is not affected by the value of TTBR0_EL3.CnP on those other PEs.

0b1 The translation table entries pointed to by TTBR0_EL3 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1 and the translation table entries are pointed to by TTBR0_EL3.

This field is permitted to be cached in a TLB.

This field resets to an architecturally UNKNOWN value.
Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL3

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

</tbody>
</table>
D12.2.114  TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL1&0 stage 1 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register TTBR1_EL1[63:0] is architecturally mapped to AArch32 System register TTBR1[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

 TTBR1_EL1 is a 64-bit register.

**Field descriptions**

The TTBR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID, bits [63:48]</td>
<td>An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID. If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Note**

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL1.IPS is 0b110, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
• Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.
• In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

--- Note ---

• In an implementation that includes ARMv8.2-LPA a TCR_EL1.IPS value of 0b110, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.
• When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL1.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not 0b110 then:
• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

--- Note ---

This definition applies:
• To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
• To any implementation that does not include ARMv8.2-LPA.

If any TTBR1_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR1_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T1SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1.

0b0 The translation table entries pointed to by TTBR1_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR1_EL1 for other PEs in the Inner Shareable domain. This is not affected by:
• The value of TTBR1_EL1.CnP on those other PEs.
• The value of the current ASID.
• If EL2 is enabled in the current Security state, the value of the current VMID.

0b1 The translation table entries pointed to by TTBR1_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1 and all of the following apply:
• The translation table entries are pointed to by TTBR1_EL1.
• The translation tables relate to the same translation regime.
• The ASID is the same as the current ASID.
• If EL2 is enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.
When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note
If the value of the TTBR1_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONstrained UNpredictable, see CONstrained UNpredictable behaviors due to caching of control or data values on page K1-7218.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Accessing the TTBR1_EL1
This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:

</table>
When `HCR_EL2.E2H` is 1, without explicit synchronization, access from EL3 using the mnemonic `TTBR1_EL1` or `TTBR1_EL12` are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If IsUsingAccess(TTBR1_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccess(TTBR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAccess(TTBR1_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.TVM == 1, then write accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccess(TTBR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && IsUsingAccess(TTBR1_EL12) && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAccess(TTBR1_EL1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && IsUsingAccess(TTBR1_EL12) && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccess(TTBR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1 || HCR_EL2.NV == 0) && IsUsingAccess(TTBR1_EL12) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.TRVM == 1, then read accesses at EL1 are trapped to EL2.

— If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.TGE == 0 && HCR_EL2.TVM == 1, then accesses at EL1 are trapped to EL2.
D12.2.115  TTBR1_EL2, Translation Table Base Register 1 (EL2)

The TTBR1_EL2 characteristics are:

**Purpose**

When HCR_EL2.E2H is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL2&0 translation regime, and other information for this translation regime.

--- Note ---

When HCR_EL2.E2H is 0, the contents of this register are ignored by the PE, except for a direct read or write of the register.

**Configurations**

This register is present only from ARMv8.1. Otherwise, direct accesses to TTBR1_EL2 are Undefined.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

TTBR1_EL2 is a 64-bit register.

**Field descriptions**

The TTBR1_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
</table>
| ASID, bits [63:48] | An ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

--- Note ---

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granularity.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.
In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL2.IPS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

--- Note ---

- In an implementation that includes ARMv8.2-LPA a TCR_EL2.IPS value of 0b110, that selects an OA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL2.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

--- Note ---

If the Effective value of TCR_EL2.IPS is not 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

--- Note ---

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

---

If any TTBR1_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR1_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[5-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T1SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL2.CnP is 1.

0b0  The translation table entries pointed to by TTBR1_EL2 for the current ASID are permitted to differ from corresponding entries for TTBR1_EL2 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR1_EL2.CnP on those other PEs.
- The value of the current ASID.

0b1  The translation table entries pointed to by TTBR1_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL2.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR1_EL2.
- The ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

Note

- TTBR1_EL2 is accessible only when the value of HCR_EL2.E2H is 1, meaning the current translation regime is the EL2&0 regime.
- If the value of the TTBR1_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL2s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7218.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR1_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTBR1_EL2</td>
<td>0010</td>
<td>11</td>
<td>100</td>
<td>001</td>
<td>000</td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>0010</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>TTBR1_EL2</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>TTBR1_EL2</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR1_EL2</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TTBR1_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR1_EL2 or TTBR1_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

If an_EL1 accessor is used, refer to TTBR1_EL1 for information on the effect of HCR_EL2.NV2 on this accessor.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

---

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

---

If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.116  VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to EL1.

**Configurations**

AArch64 System register VBAR_EL1[31:0] is architecturally mapped to AArch32 System register VBAR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VBAR_EL1 is a 64-bit register.

**Field descriptions**

The VBAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-11</td>
<td>Vector Base Address</td>
</tr>
<tr>
<td>10-0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Bits [63:11]**

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

If the implementation does not support **ARMv8.2-LVA**, then:

- If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If the implementation supports **ARMv8.2-LVA**, then:

- If tagged addresses are being used, bits [55:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

This field resets to an architecturally UNKNOWN value.

**Bits [10:0]**

Reserved, RES0.

**Accessing the VBAR_EL1**

This register can be written using MSR (register) with the following syntax:

`MSR <systemreg>, <Xt>`

This register can be read using MRS with the following syntax:

`MRS <Xt>, <systemreg>`
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

</table>
VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

**Purpose**

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by EL1 reads of MPIDR_EL1.

**Configurations**

AArch64 System register VMPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VMPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MPIDR_EL1, and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VMPIDR_EL2 is a 64-bit register.

**Field descriptions**

The VMPIDR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:40</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>39:32</td>
<td>Affinity level 3. See the description of Aff0 for more information. Aff3 is not supported in AArch32 state. This field resets to an architecturally UNKNOWN value.</td>
<td></td>
</tr>
<tr>
<td>31</td>
<td>Reserved, RES1</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are: 0b0 Processor is part of a multiprocessor system. 0b1 Processor is part of a uniprocessor system. This field resets to an architecturally UNKNOWN value.</td>
<td></td>
</tr>
<tr>
<td>29:25</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
</tbody>
</table>
MT, bit [24]
Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:
- 0b0 Performance of PEs at the lowest affinity level is largely independent.
- 0b1 Performance of PEs at the lowest affinity level is very interdependent.
This field resets to an architecturally UNKNOWN value.

Aff2, bits [23:16]
Affinity level 2. See the description of Aff0 for more information.
This field resets to an architecturally UNKNOWN value.

Aff1, bits [15:8]
Affinity level 1. See the description of Aff0 for more information.
This field resets to an architecturally UNKNOWN value.

Aff0, bits [7:0]
Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR, {Aff2, Aff1, Aff0} or MPIDR_EL1, {Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.
This field resets to an architecturally UNKNOWN value.

Accessing the VMPIDR_EL2
This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMPIDR_EL2</td>
<td>11</td>
<td>0000</td>
<td>100</td>
<td>101</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If \( \text{HCR}_{\text{EL2}.NV2} = 0 \) && \( \text{SCR}_{\text{EL3}.NS} = 1 \) \( \text{||} \) \( \text{SCR}_{\text{EL3}.EEL2} = 1 \) && \( \text{IsUsingAArch64}(\text{EL2}) \) && \( \text{HCR}_{\text{EL2}.E2H} = 0 \) && \( \text{HCR}_{\text{EL2}.NV} = 1 \), then accesses at EL1 are trapped to EL2.

— If \( \text{HCR}_{\text{EL2}.NV2} = 0 \) && \( \text{SCR}_{\text{EL3}.NS} = 1 \) \( \text{||} \) \( \text{SCR}_{\text{EL3}.EEL2} = 1 \) && \( \text{IsUsingAArch64}(\text{EL2}) \) && \( \text{HCR}_{\text{EL2}.E2H} = 1 \) && \( \text{HCR}_{\text{EL2}.TGE} = 0 \) && \( \text{HCR}_{\text{EL2}.NV} = 1 \), then accesses at EL1 are trapped to EL2.
D12.2.120 VNCR_EL2, Virtual Nested Control Register

The VNCR_EL2 characteristics are:

**Purpose**

When ARMv8.4-NV is implemented, holds the base address that is used to define the memory location that is accessed by transformed reads and writes of System registers.

**Configurations**

This register is present only when ARMv8.4-NV is implemented. Otherwise, direct accesses to VNCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VNCR_EL2 is a 64-bit register.

**Field descriptions**

The VNCR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>53</th>
<th>52</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RESS</strong></td>
<td></td>
<td></td>
<td><strong>BADDR</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td><strong>RES0</strong></td>
</tr>
</tbody>
</table>

**RESS, bits [63:53]**

Reserved, Sign extended. If the bits marked as RESS do not all have the same value, then there is a CONstrained unpredictable choice between:

- Generating an EL2 translation regime Translation abort on use of the VNCR_EL2 register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes other than reading back the register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52] for all purposes other than reading back the register.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52].

Where the EL2 translation regime has upper and lower address ranges, bit[52] is used to select between those address ranges to determine if the address space supports more than 48 bits.

**BADDR, bits [52:12]**

Base Address. If the virtual address space for EL2 does not support more than 48 bits, then bits [52:49] are RESS.

When a register read/write is transformed to be a Load or Store, the address of the load/store is to SignOffset(VNCR.BADDR:Offset<11:0>, 64).

This field resets to an architecturally UNKNOWN value.

**Bits [11:0]**

Reserved, RES0.

**Accessing the VNCR_EL2**

This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VNCR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.2.121 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

**Purpose**

Holds the value of the Virtualization Processor ID. This is the value returned by EL1 reads of MIDR_EL1.

**Configurations**

AArch64 System register VPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MIDR_EL1, and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VPIDR_EL2 is a 64-bit register.

**Field descriptions**

The VPIDR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
<th>Value</th>
<th>Implementer Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bit [31:24]</td>
<td>Implementer code</td>
<td>0x41-0x4E</td>
<td>ARM Limited, Broadcom Corp.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ARM Ltd.</td>
<td></td>

<tr>
<td>Bit [15:4]</td>
<td>Part number</td>
<td>0x00-0xFF</td>
<td></td>
</tr>
<tr>
<td>Bit [4]</td>
<td>Revision code</td>
<td>0x00-0xFF</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corp.</td>
</tr>
</tbody>
</table>
### Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field resets to an architecturally UNKNOWN value.

### Architecture, bits [19:16]

The permitted values of this field are:

- `0b0001` ARMv4.
- `0b0010` ARMv4T.
- `0b0011` ARMv5 (obsolete).
- `0b0100` ARMv5T.
- `0b0101` ARMv5TE.
- `0b0110` ARMv5TEJ.
- `0b0111` ARMv6.
- `0b1111` Architectural features are individually identified in the ID_* registers, see [ID registers on page K13-7414](#).

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

### PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are `0x0` or `0x7`, the variant and architecture are encoded differently.

This field resets to an architecturally UNKNOWN value.

### Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

This field resets to an architecturally UNKNOWN value.

### Accessing the VPIDR_EL2

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPIDR_EL2</td>
<td>11</td>
<td>0000</td>
<td>100</td>
<td>000</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-     -    n/a    RW</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If HCR_EL2.NV == 0 && SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If HCR_EL2.NV == 0 && SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.122   VSTCR_EL2, Virtualization Secure Translation Control Register

The VSTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the Secure EL1&0 translation regime.

Configurations

This register is present only from ARMv8.4. Otherwise, direct accesses to VSTCR_EL2 are UNDEFINED.

If Secure EL2 is not implemented, this register is UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.4.

Attributes

VSTCR_EL2 is a 64-bit register.

Field descriptions

The VSTCR_EL2 bit assignments are:

Any of the bits in VSTCR_EL2 are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.

**SA, bit [30]**

Secure stage 2 translation output address space.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>All stage 2 translations for the Secure IPA space access the Secure PA space.</td>
</tr>
<tr>
<td>0b1</td>
<td>All stage 2 translations for the Secure IPA space access the Non-secure PA space.</td>
</tr>
</tbody>
</table>

When the value of VSTCR_EL2.SW is 1, this bit behaves as 1 for all purposes other than reading back the value of the bit.

This field resets to an architecturally UNKNOWN value.

**SW, bit [29]**

Secure stage 2 translation address space.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>All stage 2 translation table walks for the Secure IPA space are to the Secure PA space.</td>
</tr>
<tr>
<td>0b1</td>
<td>All stage 2 translation table walks for the Secure IPA space are to the Non-secure PA space.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.
Bits [28:16]

Reserved, RES0.

TG0, bits [15:14]

Secure stage 2 granule size for VSTTBR_EL2.

- **0b00**: 4KB.
- **0b01**: 64KB.
- **0b10**: 16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then for all purposes other than read back from this register, the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Bits [13:8]

Reserved, RES0.

SL0, bits [7:6]

From ARMv8.4, when ARMv8.4-TTST is implemented:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

- **0b00**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.
- **0b01**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.
- **0b10**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.
- **0b11**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 3.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

- **0b00**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.
- **0b01**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.
- **0b10**: If VSTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VSTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

T0SZ, bits [5:0]

The size offset of the memory region addressed by VSTTBR_EL2. The region size is 2**(64-VSTCR_EL2.T0SZ) bytes.
The maximum and minimum possible values for this field depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

**Accessing the VSTCR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSTCR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>010</td>
<td>0110</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 1 &amp;&amp; HCR_EL2.TGE == 0</td>
<td>-</td>
</tr>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 1 &amp;&amp; HCR_EL2.TGE == 1</td>
<td>-</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; SCR_EL3.NS == 1 &amp;&amp; HCR_EL2.TGE == 0</td>
<td>-</td>
</tr>
<tr>
<td>SCR_EL3.NS == 1 &amp;&amp; HCR_EL2.TGE == 1</td>
<td>-</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If $HCR_{EL2}.NV2 == 0 \&\& SCR_{EL3}.NS == 0 \&\& SCR_{EL3}.EEL2 == 1 \&\& $ IsUsingAArch64(EL2) $\&\& HCR_{EL2}.E2H == 0 \&\& HCR_{EL2}.NV == 1$, then accesses at EL1 are trapped to EL2.

— If $HCR_{EL2}.NV2 == 0 \&\& SCR_{EL3}.NS == 0 \&\& SCR_{EL3}.EEL2 == 1 \&\& $ IsUsingAArch64(EL2) $\&\& HCR_{EL2}.E2H == 1 \&\& HCR_{EL2}.TGE == 0 \&\& HCR_{EL2}.NV == 1$, then accesses at EL1 are trapped to EL2.
D12.2.123  VSTTBR_EL2, Virtualization Secure Translation Table Base Register

The VSTTBR_EL2 characteristics are:

Purpose

The base register for stage 2 of the Secure EL1&0 translation regime. Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Secure EL1&0 translation regime, and other information for this translation stage.

Configurations

This register is present only from ARMv8.4. Otherwise, direct accesses to VSTTBR_EL2 are UNDEFINED.

If Secure EL2 is not implemented, this register is UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.4.

Attributes

VSTTBR_EL2 is a 64-bit register.

Field descriptions

The VSTTBR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>BADDR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

Any of the bits in VSTTBR_EL2 are permitted to be cached in a TLB.

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x].

If the value of VTCR_EL2.PS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
• When \(x > 6\) register bits[(x-1):6] are RES0.
• Register bit[1] is RES0.
• Bits[5:2] of the stage 1 translation table base address are zero.

--- Note ---

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of VTCR_EL2.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of VTCR_EL2.PS is not 0b110 then:

• Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
• Register bits[(x-1):1] are RES0.
• If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

If any VSTTBR_EL2[47:1] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VSTTBR_EL2, then the translation table base address might be misaligned, with effects that are constrained unpredictable, and must be one of the following:

• Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how \(x\) is calculated based on the value of VSTCR_EL2.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

**CnP, bit [0]**

Common not Private, for stage 2 of the Secure EL1&0 translation regime. In an implementation that includes ARMv8.2-TTCNP, indicates whether each entry that is pointed to by VSTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1.

0b0 The translation table entries pointed to by VSTTBR_EL2 are permitted to differ from the entries for VSTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

0b1 The translation table entries pointed to by VSTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

--- Note ---

If the value of VSTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VSTTBR_EL2s do not point to the same translation table entries when using the current VMID, then the results of translations using VSTTBR_EL2 are constrained predictable, see constrained unpredictable behaviors due to caching of control or data values on page K1-6254.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**Accessing the VSTTBR_EL2**

This register can be written using MSR (register) with the following syntax:

```plaintext
MSR <systemreg>, <Xt>
```
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSTTBR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>000</td>
<td>0110</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>(HCR_EL2.NV = 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp; HCR_EL2.NV2 == 1 &amp; SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 1 &amp; HCR_EL2.TGE == 0</td>
<td>- [VNCR_EL2.BADDR &lt;&lt; 12 + 0x30] RW RW</td>
</tr>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 1 &amp; HCR_EL2.TGE == 1</td>
<td>- n/a RW RW</td>
</tr>
<tr>
<td>(HCR_EL2.NV = 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp; HCR_EL2.NV2 == 1 &amp; SCR_EL3.NS == 1 &amp; HCR_EL2.TGE == 0</td>
<td>- [VNCR_EL2.BADDR &lt;&lt; 12 + 0x30] - RW</td>
</tr>
<tr>
<td>SCR_EL3.NS == 1 &amp; HCR_EL2.TGE == 1</td>
<td>- n/a - RW</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If HCR_EL2.NV == 0 & SCR_EL3.NS == 0 & SCR_EL3.EEL2 == 1 & IsUsingAArch64(EL2) & HCR_EL2.E2H == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If HCR_EL2.NV == 0 & SCR_EL3.NS == 0 & SCR_EL3.EEL2 == 1 & IsUsingAAArch64(EL2) & HCR_EL2.E2H == 1 & HCR_EL2.TGE == 0 & HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.124   VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

**Purpose**

The control register for stage 2 of the EL1&0 translation regime.

**Configurations**

AArch64 System register VTCR_EL2[31:0] is architecturally mapped to AArch32 System register VTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VTCR_EL2 is a 64-bit register.

**Field descriptions**

The VTCR_EL2 bit assignments are:

![Diagram of VTCR_EL2 bit assignments](image)

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

**Bits [63:32]**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.

**NSA, bit [30]**

*From ARMv8.4:*

Non-secure stage 2 translation output address space.

- **0b0** All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Secure PA space.
- **0b1** All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Non-secure PA space.

This bit behaves as 1 for all purposes other than reading back the value of the bit when one of the following is true:

- The PE is executing in Non-secure state.
• The value of VTCR_EL2.NSW is 1.
• The value of VSTCR_EL2.SA is 1.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**NSW, bit [29]**

**From ARMv8.4:**

Non-secure stage 2 translation table address space.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&amp;0 translation regime are to the Secure PA space.</td>
</tr>
<tr>
<td>0b1</td>
<td>All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&amp;0 translation regime are to the Non-secure PA space.</td>
</tr>
</tbody>
</table>

When the PE is executing in Non-secure state, this bit behaves as 1 for all purposes other than reading back the value of the bit.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU62, bit [28]**

**When ARMv8.2-TTPBHA is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[62] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[62] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU61, bit [27]**

**When ARMv8.2-TTPBHA is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[61] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bit[61] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU60, bit [26]**

**When ARMv8.2-TTPBHA is implemented:**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bit[60] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
</tbody>
</table>
Bit[60] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table Block or Page entry.

0b0 Bit[59] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[59] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [24:23]
Reserved, RES0.

HD, bit [22]

When ARMv8.1-TTHM is implemented:
Hardware management of dirty state in stage 2 translations when EL2 is enabled in the current Security state.

0b0 Stage 2 hardware management of dirty state disabled.

0b1 Stage 2 hardware management of dirty state enabled, only if the VTCR_EL2.HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HA, bit [21]

When ARMv8.1-TTHM is implemented:
Hardware Access flag update in Non-secure and Secure stage 2 translations when EL2 is enabled in the current Security state.

0b0 Stage 2 Access flag update disabled.

0b1 Stage 2 Access flag update enabled.

Otherwise:
Reserved, RES0.

Bit [20]
Reserved, RES0.

VS, bit [19]

When ARMv8.1-VMID16 is implemented:
VMID Size.

0b0 8 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are ignored by the hardware, and treated as if they are all zeros, for every purpose except when reading back the register.
0b1  16 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are used for allocation and matching in the TLB.

If the implementation only supports an 8-bit VMID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**PS, bits [18:16]**

Physical address Size for the Second Stage of translation.

- 0b000  32 bits, 4GB.
- 0b001  36 bits, 64GB.
- 0b010  40 bits, 1TB.
- 0b011  42 bits, 4TB.
- 0b100  44 bits, 16TB.
- 0b101  48 bits, 256TB.
- 0b110  52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by VTCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

**TG0, bits [15:14]**

Granule size for the VTTBR_EL2.

- 0b0  4KB.
- 0b1  64KB.
- 0b10  16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

- 0b0  Non-shareable.
- 0b10  Outer Shareable.
- 0b11  Inner Shareable.
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

This field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

- **0b00** Normal memory, Outer Non-cacheable.
- **0b01** Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10** Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11** Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

- **0b00** Normal memory, Inner Non-cacheable.
- **0b01** Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10** Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11** Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

**SL0, bits [7:6]**

*When ARMv8.4-TTST is implemented:*

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

- **0b00** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 3.
- **0b01** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 2.
- **0b10** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 1.
- **0b11** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 3.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

- **0b00** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 3.
- **0b01** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 2.
- **0b10** If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b11 (64KB granule), start at level 1.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.
This field resets to an architecturally UNKNOWN value.

**T0SZ, bits [5:0]**

The size offset of the memory region addressed by VTTBR_EL2. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

**Accessing the VTCR_EL2**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTCR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>010</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -</td>
</tr>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
D12.2.125 VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the EL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch64 System register VTTBR_EL2[63:0] is architecturally mapped to AArch32 System register VTTBR[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VTTBR_EL2 is a 64-bit register.

**Field descriptions**

The VTTBR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMID[15:8]</td>
<td>63-56</td>
<td>The VMID for the translation table. It is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.</td>
</tr>
<tr>
<td>VMID[7:0]</td>
<td>55-48</td>
<td>The VMID for the translation table. It is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.</td>
</tr>
<tr>
<td>BADDR</td>
<td>47-1</td>
<td>Translation table base address, A[47:x] or A[51:x], bits[47:1].</td>
</tr>
</tbody>
</table>

**VMID[15:8], bits [63:56]**

*When ARMv8.1-VMID16 is implemented:*

Extension to VMID[7:0]. See VMID[7:0] for more details.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**VMID[7:0], bits [55:48]**

The VMID for the translation table.

It is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

If the implementation has an 8-bit VMID, then VMID[15:8] are RES0.

If the implementation has a 16-bit VMID, then:

- The VTCR_EL2.VS bit selects whether VMID[15:8] are ignored by the hardware for every purpose except reading back the register, or whether these bits are used for allocation and matching in the TLB.
- The 16-bit VMID is only supported when EL2 is using AArch64. This means the hardware must ignore VMID[15:8] when EL2 is using AArch32.

This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, A[47:x] or A[51:x], bits[47:1].
**Note**

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of VTCR_EL2.PS is 0b110, then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP, bit[0] of the stage 1 translation table base address is zero.

**Note**

- In an implementation that includes ARMv8.2-LPA, a VTCR_EL2.PS value of 0b110, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of VTCR_EL2.PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the *Effective value* of VTCR_EL2.PS is not 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

**Note**

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any VTTBR_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VTTBR_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VTCR_EL2.T0SZ, the stage of translation, and the translation granule size.
This field resets to an architecturally UNKNOWN value.

**CnP, bit [0]**

*When ARMv8.2-TTCNP is implemented:*

Common not Private. This bit indicates whether each entry that is pointed to by VTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1.

0b0  The translation table entries pointed to by VTTBR_EL2 are permitted to differ from the entries for VTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

0b1  The translation table entries pointed to by VTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

This field is permitted to be cached in a TLB.

_____ Note _____

If the value of VTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBR_EL2s do not point to the same translation table entries when using the current VMID then the results of translations using VTTBR_EL2 are CONstrained Unpredictable, see *

CONstrained Unpredictable* behaviors due to caching of control or data values on page K1-7218.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Accessing the VTTBR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTTBR_EL2</td>
<td>11</td>
<td>0010</td>
<td>100</td>
<td>000</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

**Configuration**

| SCR_EL3.NS == 0 & SCR_EL3.EEL2 == 0 |

**Accessibility**

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>

<td>-</td>
<td>n/a</td>
<td>RW</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If HCR_EL2.NV == 0 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>

</tbody>
</table>
D12.3 Debug registers

This section lists the Debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug registers is \( \text{op0} = \text{0b10}, \text{op1} = \{0, 3, 4\} \). Instructions for accessing debug System registers on page D11-2657 summarizes the registers in this encoding space and lists them in order of their encodings.

- In addition, the following registers in the \( \text{op0} = \text{0b11} \) encoding space are classified as Debug registers:
  - DLR_EL0.
  - DSPSR_EL0.
  - MDCR_EL2.
  - MDCR_EL3.
  - SDER32_EL3.
D12.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Configurations**

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register DBGAUTHSTATUS[31:0].

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGAUTHSTATUS_EL1 is a 64-bit register.

**Field descriptions**

The DBGAUTHSTATUS_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[7:6]</td>
<td>SNID</td>
</tr>
<tr>
<td>[5:4]</td>
<td>SID</td>
</tr>
<tr>
<td>[3:0]</td>
<td>NSID</td>
</tr>
</tbody>
</table>

**RES0**

Reserved, RES0.

**SNID, bits [7:6]**

*When ARMv8.4-Debug is implemented:*

Secure non-invasive debug.

This field has the same as DBGAUTHSTATUS_EL1.SID.

*Otherwise:*

Secure non-invasive debug.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.</td>
</tr>
<tr>
<td>0b10</td>
<td>Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>0b11</td>
<td>Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.</td>
</tr>
</tbody>
</table>

All other values are reserved.

**SID, bits [5:4]**

Secure invasive debug.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.</td>
</tr>
<tr>
<td>0b10</td>
<td>Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>0b11</td>
<td>Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.</td>
</tr>
</tbody>
</table>

All other values are reserved.
NSID, bits [3:2]

When ARMv8.4-Debug is implemented:

Non-secure non-invasive debug.

- **0b00**: Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
- **0b11**: Implemented and enabled. EL3 is implemented or the Effective value of SCR_EL3.NS is 1.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

- **0b00**: Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
- **0b10**: Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- **0b11**: Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

- **0b00**: Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
- **0b10**: Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- **0b11**: Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing the DBGAUTHSTATUS_EL1

This register can be read using MRS with the following syntax:

\[
\text{MRS } <Xt>, <systemreg>
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGAUTHSTATUS_EL1</td>
<td>10</td>
<td>0111</td>
<td>000</td>
<td>110</td>
<td>1110</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  RO  n/a  RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then read accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then read accesses at EL1 or EL2 are trapped to EL3.
### D12.3.2 DBGBCR<\texttt{n}>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<\texttt{n}>_EL1 characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint \(n\) together with value register DBGBVR<\texttt{n}>_EL1.

**Configurations**

AArch64 System register DBGBCR<\texttt{n}>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBCR<\texttt{n}>[31:0].

AArch64 System register DBGBCR<\texttt{n}>_EL1[31:0] is architecturally mapped to External register DBGBCR<\texttt{n}>_EL1[31:0].

If breakpoint \(n\) is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGBCR<\texttt{n}>_EL1 is a 64-bit register.

### Field descriptions

The DBGBCR<\texttt{n}>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-24</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>23-20</td>
<td>Breakpoint Type. Possible values are:</td>
</tr>
<tr>
<td>0000</td>
<td>Unlinked instruction address match. DBGBVR&lt;\texttt{n}&gt;_EL1 is the address of an instruction.</td>
</tr>
<tr>
<td>0001</td>
<td>As 00000, but linked to a Context matching breakpoint.</td>
</tr>
<tr>
<td>0010</td>
<td>Unlinked Context ID match. When ARMv8.1-VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR&lt;\texttt{n}&gt;_EL1.ContextID must match the CONTEXTIDR_EL2.value. Otherwise, DBGBVR&lt;\texttt{n}&gt;_EL1.ContextID must match the CONTEXTIDR_EL1 value.</td>
</tr>
<tr>
<td>0011</td>
<td>As 00100, with linking enabled.</td>
</tr>
<tr>
<td>0110</td>
<td>Unlinked CONTEXTIDR_EL1 match. DBGBVR&lt;\texttt{n}&gt;_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.</td>
</tr>
<tr>
<td>0111</td>
<td>As 01100, with linking enabled.</td>
</tr>
<tr>
<td>1000</td>
<td>Unlinked VMID match. DBGBVR&lt;\texttt{n}&gt;_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.</td>
</tr>
<tr>
<td>1001</td>
<td>As 10000, with linking enabled.</td>
</tr>
</tbody>
</table>
Unlinked VMID and Context ID match. DBGBVR<\textit{n}>_EL1.Width is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<\textit{n}>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.

As \textcolor{red}{0b1010}, with linking enabled.

Unlinked CONTEXTIDR_EL2 match. DBGBVR<\textit{n}>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.

As \textcolor{red}{0b1100}, with linking enabled.

Unlinked Full Context ID match. DBGBVR<\textit{n}>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<\textit{n}>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.

As \textcolor{red}{0b1110}, with linking enabled.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions.

For more information on the operation of the SSC, HMC, and PMC fields, and on the effect of programming this field to a reserved value, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2305 and Reserved DBGBCR<\textit{n}>_EL1.BT values on page D2-2309.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<\textit{n}>_EL1.E is 0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint \textit{n} is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields.

For more information on the operation of the SSC, HMC, and PMC fields, and the effect of programming the fields to a reserved set of values, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2305 and Reserved DBGBCR<\textit{n}>_EL1.{SSC, HMC, PMC} values on page D2-2310.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint \textit{n} is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2305.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64 only implementation, this field is reserved, RES1.
The permitted values depend on the breakpoint type.
For Address match breakpoints, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;_EL1 + 2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see Reserved DBGBCR<n>_EL1.BAS values on page D2-2311.

For more information on using the BAS field in address match breakpoints, see Using the BAS field in Address Match breakpoints on page G2-5379.

For Context matching breakpoints, this field is RES1 and ignored.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [4:3]
Reserved, RES0.

PMC, bits [2:1]
Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information see the DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2305.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]
Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0b0  Breakpoint disabled.
0b1  Breakpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGBCR<n>_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGBCR&lt;n&gt;_EL1</td>
<td>10011</td>
<td>0000</td>
<td>000</td>
<td>101</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- <CRm> is in the range 0 - 15.
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td></td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
- If the register access does not generate an exception then, if EDSCR.TDA == 1 && halting is allowed && OSLSR_EL1.OSLK == 0, then accesses to this register from EL1, EL2, and EL3 generate a Software Access debug event.
D12.3.3 \( \text{DBGBVR}_n \_\text{EL1}, \) Debug Breakpoint Value Registers, \( n = 0 - 15 \)

The DBGBVR\(_n\)_EL1 characteristics are:

**Purpose**

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint \( n \) together with control register DBGBCR\(_n\)_EL1.

**Configurations**

AArch64 System register DBGBVR\(_n\)_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR\(_n\)[31:0].

If the breakpoint is context-aware and EL2 is implemented then AArch64 System register DBGBVR\(_n\)_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR\(_n\). Otherwise there is no System register access to DBGBVR\(_n\)_EL1[63:32] from AArch32 state.

AArch64 System register DBGBVR\(_n\)_EL1[63:0] is architecturally mapped to External register DBGBVR\(_n\)_EL1[63:0].

If breakpoint \( n \) is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally unknown values. The register is not affected by a Warm reset.

**Attributes**

How this register is interpreted depends on the value of DBGBCR\(_n\)_EL1.BT.

- When DBGBCR\(_n\)_EL1.BT is \(0b000x\), this register holds a virtual address.
- When DBGBCR\(_n\)_EL1.BT is \(0b001x\), \(0b011x\), or \(0b110x\), this register holds a Context ID.
- When DBGBCR\(_n\)_EL1.BT is \(0b100x\), this register holds a VMID.
- When DBGBCR\(_n\)_EL1.BT is \(0b101x\), this register holds a VMID and a Context ID.
- When DBGBCR\(_n\)_EL1.BT is \(0b111x\), this register holds two Context ID values.

For other values of DBGBCR\(_n\)_EL1.BT, this register is RES0.

**Field descriptions**

The DBGBVR\(_n\)_EL1 bit assignments are:

*\( \text{When DBGBCR}_n \_\text{EL1}.BT = 0b000x: \)*

<table>
<thead>
<tr>
<th>63</th>
<th>53 52</th>
<th>49 48</th>
<th>VA[48:2]</th>
<th>VA[52:49]</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>48</td>
<td>49</td>
<td>50</td>
<td>52</td>
<td>53</td>
</tr>
</tbody>
</table>

\( \text{RESS[14:4]}, \) bits [63:53]

Reserved. Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

It is implementation defined whether:

- Reads return the value of the most significant bit of the VA for every bit in this field.
- Reads return the last value written.

The PE ignores this field.
VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

VA[48:2], bits [48:2]
Bits[48:2] of the address value for comparison.
When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value.
Otherwise, VA[52:49] are RESS.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]
Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b001x:

ContextID, bits [31:0]
Context ID value for comparison.
The value is compared against CONTEXTIDR_EL2 when ARMv8.1-VIHE is implemented,
HCR_EL2.E2I is 1, and either:
• The PE is executing at EL2.
• HCR_EL2.TGE is 1, the PE is executing at EL0, and EL2 is enabled in the current Security
  state.
Otherwise, the value is compared against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b011x:

ContextID, bits [31:0]
Context ID value for comparison against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
When `DBGBCR<n>_EL1.BT == 0b100x and IsExceptionLevelImplemented(EL2)`:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>40</th>
<th>39</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID[15:8]</td>
<td>VMID[7:0]</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:48]**
- Reserved, RES0.

**VMID[15:8], bits [47:40]**
- **When `ARMv8.1-VMID16 is implemented:`**
  - Extension to VMID[7:0]. See VMID[7:0] for more details.
  - On a Cold reset, this field resets to an architecturally UNKNOWN value.
- **Otherwise:**
  - Reserved, RES0.

**VMID[7:0], bits [39:32]**
- VMID value for comparison.
  - The VMID is 8 bits in the following cases:
    - EL2 is using AArch32.
    - ARMv8.1-VMID16 is not implemented.
  - **When `ARMv8.1-VMID16 is implemented` and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.**
  - VMID[15:8] is RES0 if any of the following applies:
    - The implementation has an 8-bit VMID.
    - `VTCR_EL2.VS` has a value of 0.
    - EL2 is using AArch32.
  - On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [31:0]**
- Reserved, RES0.

---

When `DBGBCR<n>_EL1.BT == 0b101x and IsExceptionLevelImplemented(EL2)`:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>40</th>
<th>39</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID[15:8]</td>
<td>VMID[7:0]</td>
<td>ContextID</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:48]**
- Reserved, RES0.

**VMID[15:8], bits [47:40]**
- **When `ARMv8.1-VMID16 is implemented:`**
  - Extension to VMID[7:0]. See VMID[7:0] for more details.
  - On a Cold reset, this field resets to an architecturally UNKNOWN value.
- **Otherwise:**
  - Reserved, RES0.
VMID[7:0], bits [39:32]

VMID value for comparison.
The VMID is 8 bits in the following cases.
  • EL2 is using AArch32.
  • ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:
  • The implementation has an 8-bit VMID.
  • VTCR_EL2.VS has a value of 0.
  • EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b110x and IsExceptionLevelImplemented(EL2):

ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b111x, IsExceptionLevelImplemented(EL2) and ARMv8.1-VHE is implemented:

ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGBVR<n>_EL1

This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>100</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

•  <CRm> is in the range 0 - 15.

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>-</td>
<td>RW</td>
<td>n/a</td>
<td>RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.

— If the register access does not generate an exception then, if EDSCR.TDA == 1 && halting is allowed && OSLSR_EL1.OSLK == 0, then accesses to this register from EL1, EL2, and EL3 generate a Software Access debug event.
D12.3.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

---

Used in conjunction with the DBGCLAIMSET_EL1 register.

**Configurations**

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMCLR[31:0].

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

**Attributes**

DBGCLAIMCLR_EL1 is a 64-bit register.

**Field descriptions**

The DBGCLAIMCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>RES0</td>
</tr>
<tr>
<td>31:8</td>
<td>RAZ/SBZ</td>
</tr>
<tr>
<td>7:0</td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to 0.

**Accessing the DBGCLAIMCLR_EL1**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:
MRS `<xT>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGCLAIMCLR_EL1</td>
<td>10</td>
<td>0111</td>
<td>000</td>
<td>110</td>
<td>1001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

**Purpose**

Used by software to set the CLAIM tag bits to 1.
The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

---

Used in conjunction with the DBGCLAIMCLR_EL1 register.

**Configurations**

AArch64 System register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMSET[31:0].

AArch64 System register DBGCLAIMSET_EL1[31:0] is architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGCLAIMSET_EL1 is a 64-bit register.

**Field descriptions**

The DBGCLAIMSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>RAZ/SBZ</td>
<td></td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

**Accessing the DBGCLAIMSET_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGCLAIMSET_EL1</td>
<td>10</td>
<td>011</td>
<td>000</td>
<td>110</td>
<td>100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -       EL1: RW  EL2: n/a  EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

**Purpose**

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

**Configurations**

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTR_TX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0] when read.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTR_TX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTR_TXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTR_RXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTR_RX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTR_RX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTR_RXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTR_RX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTR_RX_EL0[31:0] when read.

**Attributes**

DBGDTR_EL0 is a 64-bit register.

**Field descriptions**

The DBGDTR_EL0 bit assignments are:

```
  63  32  31  0
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HighWord</td>
<td>[63:32]</td>
<td>Writes to this register set DTRRX to the value in this field and do not change RXfull. Reads from this register return the value of DTRTX and do not change TXfull.</td>
</tr>
<tr>
<td>LowWord</td>
<td>[31:0]</td>
<td>Writes to this register set DTRTX to the value in this field and set TXfull to 1.</td>
</tr>
</tbody>
</table>
Accessing the DBGDTR_EL0

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGDTR_EL0</td>
<td>10</td>
<td>000</td>
<td>011</td>
<td>000</td>
<td>010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If MDSCR_EL1.TDCC == 1 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then accesses at EL0 are trapped to EL1.
— If MDSCR_EL1.TDCC == 1 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then accesses at EL0 are trapped to EL2.
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL0 or EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL0 EL1 or EL2 are trapped to EL3.
**D12.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive**

The DBGDTRRX_EL0 characteristics are:

**Purpose**
Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

**Configurations**
AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0].
AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to External register DBGDTRRX_EL0[31:0].

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**
DBGDTRRX_EL0 is a 64-bit register.

**Field descriptions**
The DBGDTRRX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Reserved, RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:0]</td>
<td>Update DTRRX</td>
</tr>
</tbody>
</table>

If RXfull is set to 1, then reads of this register return the last value written to DTRRX and clear RXfull to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRRX_EL0**
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGDTRRX_EL0</td>
<td>10</td>
<td>0000</td>
<td>011</td>
<td>000</td>
<td>0101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If MDSCR_EL1.TDCC == 1 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then read accesses at EL0 are trapped to EL1.
— If MDSCR_EL1.TDCC == 1 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then read accesses at EL0 or EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then read accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.3.8  DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

**Purpose**

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

**Configurations**

AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0].

AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0].

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGDTRTX_EL0 is a 64-bit register.

**Field descriptions**

The DBGDTRTX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Bits [31:0]</td>
<td>Return DTRTX.</td>
</tr>
</tbody>
</table>

If TXfull is set to 0, then writes of this register update the value in DTRTX and set TXfull to 1.

For the full behavior of the Debug Communications Channel, see *Chapter H4 The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRTX_EL0**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGDTRTX_EL0</td>
<td>10</td>
<td>0000</td>
<td>011</td>
<td>000</td>
<td>0101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If MDSCR_EL1.TDCC == 1 & (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 & SCR_EL3.EEL2 == 0)), then write accesses at EL0 are trapped to EL1.

— If MDSCR_EL1.TDCC == 1 & HCR_EL2.TGE == 1 & (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then write accesses at EL0 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & MDCR_EL2.TDA == 1, then write accesses at EL0 or EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) & MDCR_EL3.TDA == 1, then write accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

**Purpose**
Controls behavior of the PE on powerdown request.

**Configurations**

AArch64 System register DBGPRCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGPRCR[31:0].

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGPRCR_EL1 is a 64-bit register.

**Field descriptions**

The DBGPRCR_EL1 bit assignments are:

![Bit assignments diagram]

---

**Bits [63:1]**

Reserved, RES0.

**CORENPDRQ, bit [0]**

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

- **0b0**: If the system responds to a powerdown request, it powers down Core power domain.
- **0b1**: If the system responds to a powerdown request, it does not power down the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state.

---

**Note**

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.
Accessing the DBGPRCR_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGPRCR_EL1</td>
<td>10</td>
<td>001</td>
<td>00</td>
<td>100</td>
<td>0100</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -, EL1: RW, EL2: n/a, EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDOSA == 1, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDOSA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.10  DBGVCR32_EL2, Debug Vector Catch Register

The DBGVCR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register DBGVCR from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**

AArch64 System register DBGVCR32_EL2[31:0] is architecturally mapped to AArch32 System register DBGVCR[31:0].

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register has no effect if EL2 is not enabled in the current Security state.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGVCR32_EL2 is a 64-bit register.

**Field descriptions**

The DBGVCR32_EL2 bit assignments are:

*When IsExceptionLevelImplemented(EL3) and IsUsingAArch64(EL3):*

![Diagram of DBGVCR32_EL2 bit assignments](image)

**Bits [63:32]**

Reserved, RES0.

**NSF, bit [31]**

FIQ vector catch enable in Non-secure state.

The exception vector offset is 0x1C.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSI, bit [30]**

IRQ vector catch enable in Non-secure state.

The exception vector offset is 0x18.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [29]**

Reserved, RES0.
NSD, bit [28]
Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSP, bit [27]
Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSS, bit [26]
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [25]
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [24:8]
Reserved, RES0.

SF, bit [7]
FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]
Reserved, RES0.

SD, bit [4]
Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]
Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.
SU, bit [1]

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

When !IsExceptionLevelImplemented(EL3):

F, bit [7]
FIQ vector catch enable.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [6]
IRQ vector catch enable.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

D, bit [4]
Data Abort vector catch enable.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

P, bit [3]
Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [2]
Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [1]
Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bit [0]

Reserved, RES0.

Accessing the DBGVCR32_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGVCR32_EL2</td>
<td>10</td>
<td>0000</td>
<td>100</td>
<td>000</td>
<td>0111</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td></td>
<td>-    -    n/a  RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL2 are trapped to EL3.
D12.3.11  DBGWCR<\text{n}>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<\text{n}>_EL1 characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<\text{n}>_EL1.

**Configurations**

AArch64 System register DBGWCR<\text{n}>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWCR<\text{n}>[31:0].

AArch64 System register DBGWCR<\text{n}>_EL1[31:0] is architecturally mapped to External register DBGWCR<\text{n}>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGWCR<\text{n}>_EL1 is a 64-bit register.

**Field descriptions**

The DBGWCR<\text{n}>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-29</td>
<td>Reserved, RES0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>28-24</td>
<td>MASK</td>
<td>Address mask</td>
<td>Only objects up to 2GB can be watched using a single mask.</td>
</tr>
<tr>
<td>23-21</td>
<td>Reserved, RES0</td>
<td></td>

</tr>
<tr>
<td>19-16</td>
<td>LBN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>15-14</td>
<td>SSC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>13-5</td>
<td>BAS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4-3</td>
<td>LSC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>PAC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>E</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>HMC</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>WT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- 0b000000: No mask.
- 0b000001: Reserved.
- 0b000010: Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b111111 addressing 31 address bits (0x7FFFFFFF mask for address).

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [23:21]**

Reserved, RES0.
WT, bit [20]  
Watchpoint type. Possible values are:

0b0    Unlinked data address match.
0b1    Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]  
Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]  
Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2305, and Reserved DBGCR<El1>[SSC, HMC, PMC] values on page D2-2310.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]  
Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2316.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]  
Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<El1> is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxxxxx1</td>
<td>Match byte at DBGWVR&lt;El1&gt;</td>
</tr>
<tr>
<td>xxxxxxx1x</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 1</td>
</tr>
<tr>
<td>xxxxx1xx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 2</td>
</tr>
<tr>
<td>xxxxx1xxx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<El1> addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;El1&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxxx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 4</td>
</tr>
<tr>
<td>xx1xxxxx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 5</td>
</tr>
<tr>
<td>x1xxxxxx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 6</td>
</tr>
<tr>
<td>1xxxxxxx</td>
<td>Match byte at DBGWVR&lt;El1&gt; + 7</td>
</tr>
</tbody>
</table>

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<n>_EL1.BAS values on page D2-2325.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**LSC, bits [4:3]**

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- **0b01**: Match instructions that load from a watchpointed address.
- **0b10**: Match instructions that store to a watchpointed address.
- **0b11**: Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**PAC, bits [2:1]**

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2316.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E, bit [0]**

Enable watchpoint n. Possible values are:

- **0b0**: Watchpoint disabled.
- **0b1**: Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

### Accessing the DBGWCR<n>_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGWCR&lt;n&gt;_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>111</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- <CRm> is in the range 0 - 15.
**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) & MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.

— If the register access does not generate an exception then, if EDSCR.TDA == 1 & halting is allowed & OSLSR_EL1.OSLK == 0, then accesses to this register from EL1, EL2, and EL3 generate a Software Access debug event.
D12.3.12  DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Configurations

AArch64 System register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<n>[31:0].
AArch64 System register DBGWVR<n>_EL1[63:0] is architecturally mapped to External register DBGWVR<n>_EL1[63:0].

If breakpoint n is not implemented then this register is unallocated.
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>53 52</th>
<th>49 48</th>
<th>2 1 0</th>
</tr>
</thead>
</table>

RESS[14:4], bits [63:53]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value.
Otherwise, VA[52:49] are RESS.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGWVR&lt;n&gt;_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>110</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- <CRm> is in the range 0 - 15.

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -; EL1: RW; EL2: n/a; EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
— If the register access does not generate an exception then, if EDSCR.TDA == 1 && halting is allowed && OSLSR_EL1.OSLK == 0, then accesses to this register from EL1, EL2, and EL3 generate a Software Access debug event.
D12.3.13 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

**Purpose**

In Debug state, holds the address to restart from.

**Configurations**

AArch64 System register DLR_EL0[31:0] is architecturally mapped to AArch32 System register DLR.

**Attributes**

DLR_EL0 is a 64-bit register.

**Field descriptions**

The DLR_EL0 bit assignments are:

![Diagram of DLR_EL0 bit assignments]

**Accessing the DLR_EL0**

This register can be read using MRS with the following syntax:

\[ \text{MRS} \ <Xt>, \ <\text{systemreg}> \]

This register can be written using MSR (register) with the following syntax:

\[ \text{MSR} \ <\text{systemreg}>, \ <Xt> \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLR_EL0</td>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.
D12.3.14 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

**Purpose**

Holds the saved process state on entry to Debug state.

**Configurations**

AArch64 System register DSPSR_EL0[31:0] is architecturally mapped to AArch32 System register DSPSR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DSPSR_EL0 is a 64-bit register.

**Field descriptions**

The DSPSR_EL0 bit assignments are:

*When exiting Debug state to AArch32:*

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Field Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31</td>
<td>N, bit [31] Copied to PSTATE.N on exiting Debug state.</td>
</tr>
<tr>
<td>29</td>
<td>C, bit [29] Copied to PSTATE.C on exiting Debug state.</td>
</tr>
<tr>
<td>28</td>
<td>V, bit [28] Copied to PSTATE.V on exiting Debug state.</td>
</tr>
<tr>
<td>27</td>
<td>Q, bit [27] Copied to PSTATE.Q on exiting Debug state.</td>
</tr>
<tr>
<td>26-25</td>
<td>IT[1:0], bits [26:25] IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.</td>
</tr>
<tr>
<td>24</td>
<td>DIT, bit [24] Data Independent Timing. This bit is set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.</td>
</tr>
</tbody>
</table>

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. This bit is set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.
**Bit [23]**
Reserved, RES0.

**PAN, bit [22]**

*When ARMv8.1-PAN is implemented:*
Privileged Access Never. This bit is set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

*Otherwise:*
Reserved, RES0.

**SS, bit [21]**
Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

**IL, bit [20]**
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

**GE, bits [19:16]**
Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**
IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- **IT[7:5]** holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- **IT[4:0]** encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

**E, bit [9]**
Endianness state bit. Controls the load and store endianness for data accesses:
- **0b0** Little-endian operation
- **0b1** Big-endian operation.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the PSTATE.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**
SExternal interrupt mask bit.
- **0b0** Exception not masked.
- **0b1** Exception masked.

**I, bit [7]**
IRQ mask bit.
- **0b0** Exception not masked.
D12 AArch64 System Register Descriptions
D12.3 Debug registers

F, bit [6]

FIQ mask bit.

0b0  Exception not masked.
0b1  Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from.

0b0  Taken from A32 state.
0b1  Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from.

0b1  Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from.

0b0000  User.
0b0001  FIQ.
0b0010  IRQ.
0b0011  Supervisor.
0b0110  Monitor.
0b0111  Abort.
0b1010  Hyp.
0b1011  Undefined.
0b1111  System.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.

When entering Debug state from AArch64 and exiting Debug state to AArch64:

| 63 | 32:31 | 30 | 29 | 28 | 27 | 26:25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|-------|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | N | Z | C | V | RES0 | SS | IL | RES0 | D | A | I | F | M[3:0] |

DIT

| UAO | M[4] | RES0 | PAN |

Bits [63:32]

Reserved, RES0.

N, bit [31]

Set to the value of the N condition flag on entering Debug state, and copied to the N condition flag on exiting Debug state.
Z, bit [30]
Set to the value of the Z condition flag on entering Debug state, and copied to the Z condition flag on exiting Debug state.

C, bit [29]
Set to the value of the C condition flag on entering Debug state, and copied to the C condition flag on exiting Debug state.

V, bit [28]
Set to the value of the V condition flag on entering Debug state, and copied to the V condition flag on exiting Debug state.

Bits [27:25]
Reserved, RES0.

DIT, bit [24]
*When ARMv8.4-DIT is implemented:*
Data Independent Timing. This bit is set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

*Otherwise:*
Reserved, RES0.

UAO, bit [23]
*When ARMv8.2-UAO is implemented:*
User Access Override. This bit is set to the value of PSTATE.UAO on entering Debug state, and copied to PSTATE.UAO on exiting Debug state.

*Otherwise:*
Reserved, RES0.

PAN, bit [22]
*When ARMv8.1-PAN is implemented:*
Privileged Access Never. This bit is set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

*Otherwise:*
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

Bits [19:10]
Reserved, RES0.

D, bit [9]
Process state D mask.
- 0b0 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
- 0b1 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.
A, bit [8]
SEReport interrupt mask bit.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

Accessing the DSPSR_EL0

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSPSR_EL0</td>
<td>11</td>
<td>0100</td>
<td>011</td>
<td>000</td>
<td>0101</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>RW RW n/a RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.
D12.3.15 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

**Purpose**

Enables interrupt requests to be signaled based on the DCC status flags.

**Configurations**

AArch64 System register MDCCINT_EL1[31:0] is architecturally mapped to AArch32 System register DBGDCCINT[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MDCCINT_EL1 is a 64-bit register.

**Field descriptions**

The MDCCINT_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>RX, bit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>29</td>
<td>TX, bit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>28</td>
<td>Reserved, RES0.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:31]**

Reserved, RES0.

**RX, bit [30]**

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- **0b0**: No interrupt request generated by DTRRX.
- **0b1**: Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to 0.

**TX, bit [29]**

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- **0b0**: No interrupt request generated by DTRTX.
- **0b1**: Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to 0.

**Bits [28:0]**

Reserved, RES0.

**Accessing the MDCCINT_EL1**

This register can be written using MSR (register) with the following syntax:
MSR `<systemreg>, <Xt>`

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCCINT_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>000</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW, EL1: n/a, EL2: RW, EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) & IsUsingAArch64(EL2) & MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) & MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.16   MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

**Purpose**
Read-only register containing control status flags for the DCC.

**Configurations**
AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to External register EDSCR[30:29].
AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to AArch32 System register DBGDSCRint[30:29].
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
MDCCSR_EL0 is a 64-bit register.

**Field descriptions**
The MDCCSR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>RXfull, bit [30]</td>
</tr>
<tr>
<td>31:29</td>
<td>DTRRX full. Read-only view of the equivalent bit in the EDSCR.</td>
</tr>
<tr>
<td>28:19</td>
<td>TXfull, bit [29]</td>
</tr>
<tr>
<td>18:15</td>
<td>DTRTX full. Read-only view of the equivalent bit in the EDSCR.</td>
</tr>
<tr>

<td>Reserved, RAZ.</td>
</tr>
<tr>
<td>11:6</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>5:2</td>
<td>Reserved, RAZ.</td>
</tr>
</tbody>
</table>
Bits [1:0]

Reserved, RES0.

Accessing the MDCCSR_EL0

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCCSR_EL0</td>
<td>10</td>
<td>0000</td>
<td>011</td>
<td>000</td>
<td>001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>RO RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If MDSCR_EL1.TDCC == 1 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then read accesses at EL0 are trapped to EL1.

— If MDSCR_EL1.TDCC == 1 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.

— If MDSCR_EL1.TDCC == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then read accesses at EL0 or EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then read accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

**Purpose**

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

**Configurations**

AArch64 System register MDCR_EL2[31:0] is architecturally mapped to AArch32 System register HDCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MDCR_EL2 is a 64-bit register.

**Field descriptions**

The MDCR_EL2 bit assignments are:

```plaintext
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>RES0</td>

<tr>
<td>49</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>48</td>
<td>TRFCR_EL1</td>
</tr>
</tbody>
</table>
```

**Bits [63:20]**

Reserved, RES0.

**TTRF, bit [19]**

*When ARMv8.4-Trace is implemented:*

Traps use of the Trace Filter Control registers at EL1 to EL2.

- **0b0** Accesses to TRFCR_EL1 and TRFCR at EL1 are not affected by this control.
- **0b1** Accesses to TRFCR_EL1 and TRFCR at EL1 generate a trap exception to EL2 when it is enabled in the current Security state.

*Otherwise:*

Reserved, RES0.

**Bit [18]**

Reserved, RES0.
HPMD, bit [17]

From ARMv8.1:

Guest Performance Monitors Disable. This control prohibits event counting at EL2.

\[ \begin{align*}
0b0 & \quad \text{Event counting allowed at EL2.} \\
0b1 & \quad \text{Event counting prohibited at EL2.}
\end{align*} \]

In an ARMv8.1 implementation, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface

ExternalSecureNoninvasiveDebugEnabled().

This control applies only to:

- The event counters in the range \([0..(HPMN-1)]\).
- If PMCR_EL0.DP is set to 1, PMCCNTR_EL0.

The other event counters are unaffected, and when PMCR_EL0.DP is set to 0, PMCCNTR_EL0 is unaffected.

On a Warm reset, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [16:15]

Reserved, RES0.

TPMS, bit [14]

From ARMv8.2:

Trap Performance Monitor Sampling. When the Statistical Profiling Extension is implemented, this field controls access to Statistical Profiling control registers from EL1.

\[ \begin{align*}
0b0 & \quad \text{Do not trap Statistical Profiling controls to EL2.} \\
0b1 & \quad \text{Accesses to Statistical Profiling controls at EL1 generate a Trap exception to EL2 when it is enabled in the current Security state.}
\end{align*} \]

When the Statistical Profiling Extension is not implemented, this field is reserved, RES0.

Otherwise:

Reserved, RES0.

E2PB, bits [13:12]

From ARMv8.2:

EL2 Profiling Buffer. When the Statistical Profiling Extension is implemented, this field controls the owning translation regime and access to Profiling Buffer control registers from EL1.

\[ \begin{align*}
0bb0 & \quad \text{Profiling Buffer uses the EL2 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 generate a Trap exception to EL2 when it is enabled in the current Security state.} \\
0bb1 & \quad \text{Profiling Buffer uses the EL1&0 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 generate a Trap exception to EL2 when it is enabled in the current Security state.} \\
0b11 & \quad \text{Profiling Buffer uses the EL1&0 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 are not trapped.}
\end{align*} \]

All other values are reserved. If this field is programmed with a reserved value, the PE behaves as if this field has a defined value, other than for a direct read of the register. Software must not rely on the behavior of reserved values, as they might change in a future version of the architecture.

If EL2 is not implemented, or is disabled in the current Security State, the PE behaves as if E2PB == 0b11, other than for a direct read of the register.

When the Statistical Profiling Extension is not implemented, this field is RES0.
Otherwise:
Reserved, RES0.

TDRA, bit [11]
Trap Debug ROM Address register access. Traps System register accesses to the Debug ROM registers to EL2 when it is enabled in the current Security state. This trap is from:
- EL0 using AArch32.
- EL1, regardless of which Execution state it is using.
  0b0  This control does not cause any instructions to be trapped.
  0b1  EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2 when it is enabled in the current Security state, unless it is trapped by DBGDSCRext.UDCCdis or MDSCR_EL1.TDCC.
The registers for which accesses are trapped are as follows:
AArch64: MDRAR_EL1.
AArch32: DBGDRAR, DBGDSAR.
This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:
- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.
- When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDOSA, bit [10]
When ARMv8.0-DoubleLock is implemented:
Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states:
  0b0  This control does not cause any instructions to be trapped.
  0b1  EL1 System register accesses to the powerdown debug registers are trapped to EL2 when it is enabled in the current Security state.
The registers for which accesses are trapped are as follows:
AArch64: OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and DBGPRCR_EL1.
AArch32: DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note
These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:
- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.
- When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states:
  0b0  This control does not cause any instructions to be trapped.
EL1 System register accesses to the powerdown debug registers are trapped to EL2 when it is enabled in the current Security state.

The registers for which accesses are trapped are as follows:
- AArch64: OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
- AArch32: DBGOSLSR, DBGOSLAR, and DBGPRCR.
- AArch64 and AArch32: Any implementation defined register with similar functionality that the implementation specifies as trapped by this bit.

It is implementation defined whether accesses to OSDLR_EL1 and DBGOSDLR are trapped.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.
- When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0.

On a Warm reset, this field resets to an architecturally unknown value.

TDA, bit [9]

Trap Debug Access. Traps EL0 and EL1 System register accesses to those debug System registers that are not trapped by either of the following:

- MDCR_EL2.TDRA.
- MDCR_EL2.TDOSA.

This control does not cause any instructions to be trapped.

0b1 EL0 or EL1 System register accesses to the debug registers are trapped from both Execution states to EL2 when it is enabled in the current Security state, unless the access generates a higher priority exception.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1
- HCR_EL2.TGE == 1
- When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0.

On a Warm reset, this field resets to an architecturally unknown value.

TDE, bit [8]

Trap Debug exceptions.

This control has no effect on the routing of debug exceptions, and has no effect on accesses to debug registers.

Debug exceptions generated at EL1 or EL0 are routed to EL2 when it is enabled in the current Security state. The MDCR_EL2.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- HCR_EL2.TGE == 1.
- When EL2 is enabled in the current Security state and the value of HCR_EL2.E2H is 0.

On a Warm reset, this field resets to an architecturally unknown value.
HPME, bit [7]
Hypervisor Performance Monitors Counters Enable.
0b0    EL2 Performance Monitors counters disabled.
0b1    EL2 Performance Monitors counters enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from EL2 or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors Extension is not implemented, this field is RES0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPM, bit [6]
Trap Performance Monitors accesses. Traps EL0 and EL1 accesses to all Performance Monitors registers to EL2 when it is enabled in the current Security state, from both Execution states:
0b0    This control does not cause any instructions to be trapped.
0b1    EL0 and EL1 accesses to all Performance Monitors registers are trapped to EL2 when it is enabled in the current Security state.

Note
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPMCR, bit [5]
Trap PMCR_EL0 or PMCR accesses. Traps EL0 and EL1 accesses to the PMCR_EL0 or PMCR to EL2 when it is enabled in the current Security state.
0b0    This control does not cause any instructions to be trapped.
0b1    EL0 and EL1 accesses to the PMCR_EL0 or PMCR are trapped to EL2 when it is enabled in the current Security state, unless it is trapped by PMUSERENR.EN or PMUSERENR_EL0.EN.

Note
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

HPMN, bits [4:0]
Defines the number of Performance Monitors counters that are accessible from EL2 and EL3.

If the Performance Monitors Extension is not implemented, this field is RES0.

HPMN divides the Performance Monitors into two ranges: [0:(HPMN-1)] and [HPMN:PMCR_EL0.N].

For an event in the range [0:(HPMN-1)]:
- The counter is accessible from EL3, EL2, and EL1, and from EL0 if permitted by PMUSERENR_EL0 or PMUSERENR.
- The counter is enabled by PMCR_EL0.E and PMCNTENSEL_EL0.

For an event in the range [HPMN:PMCR_EL0.N]:
- The counter is accessible only from EL2 and EL3.
- If ARMv8.4-SecEL2 is not implemented, the count is also accessible from Secure EL1 and from Secure EL0 if permitted by PMUSERENR_EL0.
The counter is enabled by MDCR_EL2.HPME and PMCNTENSEL_EL0.
If this field is set to 0, or to a value larger than PMCR_EL0.N, then the following constrained unpredictable behavior applies:

- The value returned by a direct read of MDCR_EL2.HPMN is unknown.
- Either:
  - An unknown number of counters are reserved for EL2 and EL3 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an unknown non-zero value less than PMCR_EL0.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

On a warm reset, this field resets to the value in PMCR_EL0.N.

**Accessing the MDCR_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <xt>

This register can be read using MRS with the following syntax:

MRS <xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL2</td>
<td>11</td>
<td>001</td>
<td>100</td>
<td>001</td>
<td>001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.* Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && HCR_EL2.E2H == 1 && HCR_EL2.TGE == 0 && HCR_EL2.NV == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL2 are trapped to EL3.
D12.3.18 MDCR_EL3, Monitor Debug Configuration Register (EL3)

The MDCR_EL3 characteristics are:

**Purpose**
Provides EL3 configuration options for self-hosted debug and the Performance Monitors Extension.

**Configurations**
AArch64 System register MDCR_EL3[31:0] can be mapped to AArch32 System register SDCR[31:0], but this is not architecturally mandated.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
MDCR_EL3 is a 64-bit register.

**Field descriptions**
The MDCR_EL3 bit assignments are:

![Diagram of MDCR_EL3 bit assignments]

**Bits [63:22]**
Reserved, RES0.

**EPMAD, bit [21]**

*When ARMv8.4-Debug is implemented:*

External debug interface Performance Monitors registers disable. This disables Non-secure access to these registers by an external debugger.

- 0b0: Non-secure access to Performance Monitors registers from external debugger is enabled.
- 0b1: Non-secure access to Performance Monitors registers from external debugger is disabled.

If the Performance Monitors Extension is not implemented, or does not support external debug interface accesses this bit is RES0.

If EL3 and EL2 are not implemented and the *Effective value* of SCR_EL3.NS is 0b0, then the *Effective value* of this bit is 0b1.

On a Warm reset, this field resets to 0.
From ARMv8.0:
External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger.

0b0 Access to Performance Monitors registers from external debugger is enabled.
0b1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension is not implemented, or does not support external debug interface accesses this bit is RES0.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

Otherwise:
Reserved, RES0.

EDAD, bit [20]

When ARMv8.4-Debug is implemented:
External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger.

0b0 Non-secure access to debug registers from external debugger is enabled.
0b1 Non-secure access to breakpoint and watchpoint registers, and OSLAR_EL1 from external debugger is disabled.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.

When ARMv8.2-Debug is implemented:
External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger.

0b0 Access to debug registers, and to OSLAR_EL1 from external debugger is enabled.
0b1 Access to breakpoint and watchpoint registers, and to OSLAR_EL1 from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.

From ARMv8.0:
External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger.

0b0 Access to debug registers from external debugger is enabled.
0b1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

It is IMPLEMENTATION DEFINED whether this disable applies to the external register OSLAR_EL1.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this field is 0b1.

On a Warm reset, this field resets to 0.

Otherwise:
Reserved, RES0.
TTRF, bit [19]

When ARMv8.4-Trace is implemented:

Trap Trace Filter controls. Traps use of the Trace Filter control registers at EL2 and EL1 to EL3.

0b0  Accesses to TRFCR_EL2, TRFCR_EL12, TRFCR_EL1, HTRFCR and TRFCR registers at EL2 and EL1 are not affected by this control.

0b1  Accesses to TRFCR_EL2, TRFCR_EL12, TRFCR_EL1, HTRFCR and TRFCR registers at EL2 and EL1 generate a Trap exception to EL3.

Otherwise:
Reserved, RES0.

STE, bit [18]

When ARMv8.4-Trace is implemented:

Secure Trace enable. Enables tracing in Secure state.

0b0  Trace prohibited in Secure state unless overridden by the external debugger.

0b1  Trace allowed in Secure state unless prohibited by the Trace Filter control registers.

This bit also controls the level of authentication required by an external debugger to enable external tracing. If EL3 is not implemented and the PE is executing in Secure state, the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

Otherwise:
Reserved, RES0.

SPME, bit [17]

Secure Performance Monitors enable. This allows event counting in Secure state.

0b0  Event counting prohibited in Secure state.

In an ARMv8.0 or ARMv8.1 implementation, event counting is prohibited unless ExternalSecureNoninvasiveDebugEnabled() is TRUE, meaning this control is overridden by the IMPLEMENTATION DEFINED authentication interface.

0b1  Event counting allowed in Secure state.

If the Performance Monitors Extension is not implemented, this field is RES0.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is 0b0, then the Effective value of this bit is 0b1.

On a Warm reset, this field resets to 0.

SDD, bit [16]

AArch64 Secure self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Breakpoint Instruction exceptions.

0b0  Debug exceptions from Secure EL0 are enabled, and debug exceptions from Secure EL1 are enabled if the value of MDSCR_EL1.KDE is 1 and the value of PSTATE.D is 0.

0b1  Debug exceptions, other than Breakpoint Instruction exceptions, are disabled from all Exception levels in Secure state.

The SDD bit is ignored unless both of the following are true:

•  The PE is in Secure state.

•  The Effective value of SCR_EL3.RW is 0b0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
SPD32, bits [15:14]

AArch32 Secure self-hosted privileged invasive debug control. Enables or disables debug exceptions from Secure EL1 using AArch32, other than Breakpoint Instruction exceptions. Valid values for this field are:

- **0b00**: Legacy mode. Debug exceptions from Secure EL1 are enabled by the IMPLEMENTATION DEFINED authentication interface.
- **0b10**: Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
- **0b11**: Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as **0b00**. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field has no effect on Breakpoint Instruction exceptions. These are always enabled.

This field is:

- Ignored if the PE is either:
  - In Non-secure state.
  - In Secure state, if the Effective value of SCR_EL3.RW is **0b1**.
- **RES0** if the implementation does not support EL1 using AArch32.

If Secure EL1 is using AArch32 then:

- If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
- Otherwise, debug exceptions from Secure EL0 are enabled only if the value of SDER32_EL3.SUIDEN is **1**.

If EL3 and EL2 are not implemented and the Effective value of SCR_EL3.NS is **0b0**, then the Effective value of this field is **0b11**.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSPB, bits [13:12]

*From ARMv8.2:*

Non-secure Profiling Buffer. When the Statistical Profiling Extension is implemented, this field controls the owning translation regime and accesses to Statistical Profiling and Profiling Buffer control registers. The possible values of this field are:

- **0b00**: Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer controls at EL2 and EL1 in both security states generate Trap exceptions to EL3.
- **0b01**: Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer controls in Non-secure state generate Trap exceptions to EL3.
- **0b10**: Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer controls at EL2 and EL1 in both security states generate Trap exceptions to EL3.
- **0b11**: Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer controls in Secure state generate Trap exceptions to EL3.

If EL3 is not implemented and the PE is executing in Non-secure state, the Effective value of this field is **0b11**.

If EL3 is not implemented and the PE is executing in Secure state, the Effective value of this field is **0b01**.

When the Statistical Profiling Extension is not implemented, this field is **RES0**.
**Otherwise:**

Reserved, RES0.

**Bit [11]**

Reserved, RES0.

**TDOSA, bit [10]**

*When ARMv8.0-DoubleLock is implemented:*

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

0b0  This control does not cause any instructions to be trapped.

0b1  EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

The registers for which accesses are trapped are as follows:

AArch64: OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and DBGPRCR_EL1.

AArch32: DBGOSLAR, DBGOSLSR, DBGOSDLR, and DBGPRCR.

AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

0b0  This control does not cause any instructions to be trapped.

0b1  EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

The registers for which accesses are trapped are as follows:

AArch64: OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.

AArch32: DBGOSLAR, DBGOSLSR, and DBGPRCR.

AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to OSDLR_EL1 and DBGOSDLR are trapped.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**TDA, bit [9]**

Trap Debug Access. Traps EL2, EL1, and EL0 System register accesses to those debug System registers that cannot be trapped using the MDCR_EL3.TDOSA field. When MDCR_EL3.TDA is:

0b0  This control does not cause any instructions to be trapped.

0b1  EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA, are trapped to EL3, from both Security states and both Execution states, unless it is trapped by DBGDSCRext.UCDCedis, MDSCR_EL1.TDCC, HDCR.TDA or MDCR_EL2.TDA.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [8:7]**

Reserved, RES0.
TPM, bit [6]

Trap Performance Monitors accesses. Traps EL2, EL1, and EL0 accesses to all Performance Monitors registers to EL3, from both Security states and both Execution states.

- 0b0: This control does not cause any instructions to be trapped.
- 0b1: EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3, unless it is trapped by HDCR.TPM or MDCR_EL2.TPM.

If the Performance Monitors Extension is not implemented, this field is RES0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [5:0]

Reserved, RES0.

Accessing the MDCR_EL3

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL3</td>
<td>11</td>
<td>0001</td>
<td>110</td>
<td>001</td>
<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -; EL1: -; EL2: n/a; EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.3.19 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. ARMv8 deprecates any use of this register.

**Configurations**

AArch64 System register MDRAR_EL1[63:0] is architecturally mapped to AArch32 System register DBGDRAR[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MDRAR_EL1 is a 64-bit register.

**Field descriptions**

The MDRAR_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>52</th>
<th>51</th>
<th>48</th>
<th>47</th>
<th>12</th>
<th>11</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ROMADDR[47:12]</td>
<td>RES0</td>
<td>Valid</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:52]**

Reserved, RES0.

**ROMADDR[51:48], bits [51:48]**

**When ARMv8.2-LPA is implemented:**

**Otherwise:**

Reserved, RES0.

**ROMADDR[47:12], bits [47:12]**

Bits [47:12] of the ROM table physical address.

When ARMv8.2-LPA is implemented, ROMADDR[51:48] forms the upper part of the address value. Otherwise, ROMADDR[51:48] is RES0.

If the physical address size in bits (PAsize) is less than 52, then the register bits corresponding to ROMADDR[51:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

ARM strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

**Bits [11:2]**

Reserved, RES0.
Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

0b00  ROM Table address is not valid. Software must ignore ROMADDR.
0b11  ROM Table address is valid.

Other values are reserved.

Accessing the MDRAR_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDRAR_EL1</td>
<td>10</td>
<td>0001</td>
<td>000</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDRA == 1, then read accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then read accesses at EL1 or EL2 are trapped to EL3.
**D12.3.20 MDSCR_EL1, Monitor Debug System Control Register**

The MDSCR_EL1 characteristics are:

**Purpose**
Main control register for the debug implementation.

**Configurations**
AArch64 System register MDSCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGDSCRext[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
MDSCR_EL1 is a 64-bit register.

**Field descriptions**
The MDSCR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>

</tbody>
</table>

*When ARMv8.4-Trace is implemented:*

When the OS Lock is unlocked, OLSR_EL1.OSLK == 0, this bit ignores writes, and software must treat it as UNK/SBZP.

When the OS Lock is locked, OLSR_EL1.OSLK == 1, this bit is RW, and holds the value of EDSCR.TFO.

Reads and writes of this bit are indirect accesses to EDSCR.TFO.

*Otherwise:*
Reserved, RES0.
When `OSLSR_EL1.OSLK == 1`, this bit is RW and holds the value of EDSCR.RXfull. Reads and writes of this bit are indirect accesses to EDSCR.RXfull. The architected behavior of this field determines the value it returns after a reset.

**TXfull, bit [29]**

Used for save/restore of EDSCR.TXfull.

When `OSLSR_EL1.OSLK == 0`, this bit is RO, and software must treat it as UNK/SBZP. When `OSLSR_EL1.OSLK == 1`, this bit is RW and holds the value of EDSCR.TXfull. Reads and writes of this bit are indirect accesses to EDSCR.TXfull. The architected behavior of this field determines the value it returns after a reset.

**Bit [28]**

Reserved, RES0.

**RXO, bit [27]**

Used for save/restore of EDSCR.RXO.

When `OSLSR_EL1.OSLK == 0`, this bit is RO, and software must treat it as UNK/SBZP. When `OSLSR_EL1.OSLK == 1`, this bit is RW and holds the value of EDSCR.RXO. Reads and writes of this bit are indirect accesses to EDSCR.RXO. The architected behavior of this field determines the value it returns after a reset.

**TXU, bit [26]**

Used for save/restore of EDSCR.TXU.

When `OSLSR_EL1.OSLK == 0`, this bit is RO, and software must treat it as UNK/SBZP. When `OSLSR_EL1.OSLK == 1`, this bit is RW and holds the value of EDSCR.TXU. Reads and writes of this bit are indirect accesses to EDSCR.TXU. The architected behavior of this field determines the value it returns after a reset.

**Bits [25:24]**

Reserved, RES0.

**INTdis, bits [23:22]**

Used for save/restore of EDSCR.INTdis.

When `OSLSR_EL1.OSLK == 0`, this field is RO, and software must treat it as UNK/SBZP. When `OSLSR_EL1.OSLK == 1`, this field is RW and holds the value of EDSCR.INTdis. Reads and writes of this field are indirect accesses to EDSCR.INTdis. The architected behavior of this field determines the value it returns after a reset.

**TDA, bit [21]**

Used for save/restore of EDSCR.TDA.

When `OSLSR_EL1.OSLK == 0`, this bit is RO, and software must treat it as UNK/SBZP. When `OSLSR_EL1.OSLK == 1`, this bit is RW and holds the value of EDSCR.TDA. Reads and writes of this bit are indirect accesses to EDSCR.TDA. The architected behavior of this field determines the value it returns after a reset.

**Bit [20]**

Reserved, RES0.
SC2, bit [19]

When ARMv8.1-VHE is implemented:

Used for save/restore of EDSCR.SC2.

When OSLR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.SC2.

Reads and writes of this bit are indirect accesses to EDSCR.SC2.

If the PC Sample-based Profiling Extension is not implemented, then this field is res0.

Otherwise:

Reserved, res0.

Bits [18:16]

RAZ/WI. Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

0b0  Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
0b1  Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.
When OSLR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.HDE.

Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The architected behavior of this field determines the value it returns after a reset.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D.

Permitted values are:

0b0  Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D.
0b1  All debug exceptions enabled within EL_D.
res0 if EL_D is using AArch32.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDCC, bit [12]

Traps EL0 accesses to the DCC registers to EL1, from both Execution states.

0b0  This control does not cause any instructions to be trapped.
0b1  EL0 using AArch64: EL0 accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 registers are trapped to EL1. EL0 using AArch32: EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGIDIR, DBGDSAR, and DBGDRAR registers are trapped to EL1.

Note

All accesses to these AArch32 registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

Traps of AArch32 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.
Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [11:7]**

Reserved, RES0.

**ERR, bit [6]**

Used for save/restore of EDSCR.ERR.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.ERR.

Reads and writes of this bit are indirect accesses to EDSCR.ERR.

The architected behavior of this field determines the value it returns after a reset.

**Bits [5:1]**

Reserved, RES0.

**SS, bit [0]**

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

- 0b0 Software step disabled
- 0b1 Software step enabled.

RES0 if EL_D is using AArch32.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing the MDSCR_EL1

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDSCR_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>010</td>
<td>0010</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
</tbody>
</table>
Individual fields within this register might have restricted accessibility when OSLR_EL1.OSLK == 0 (the OS lock is unlocked). See the field descriptions for more detail.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 \&\& SCR_EL3.EEL2 == 1) \&\& IsUsingAArch64(EL2) \&\& MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) \&\& MDCR_EL3.TDA == 1, then accesses at EL2 are trapped to EL3.

— If IsUsingAArch64(EL3) \&\& MDCR_EL3.TDA == 1, then accesses at EL1 are trapped to EL3.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>(HCR_EL2.NV == 0 &amp;&amp; HCR_EL2.NV2 == 0) &amp;&amp; (SCR_EL3.NS == 1 &amp;&amp; SCR_EL3.EEL2 == 1)</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1 &amp;&amp; SCR_EL3.EEL2 == 1)</td>
<td>- [VNCR_EL2.BADDR &lt;&lt; 12 + 0x158] RW RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1 &amp;&amp; SCR_EL3.EEL2 == 1)</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>
D12.3.21   OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

**Purpose**

Used to control the OS Double Lock.

**Configurations**

AArch64 System register OSDLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSDLR[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

OSDLR_EL1 is a 64-bit register.

**Field descriptions**

The OSDLR_EL1 bit assignments are:

![Diagram of OSDLR_EL1]

---

**Bits [63:1]**

Reserved, RES0.

**DLK, bit [0]**

*When DBGDEVID.DoubleLock == 0b1:*

OS Double Lock control bit. Possible values are:

- **0b0**: OS Double Lock unlocked.
- **0b1**: OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

On a Warm reset, this field resets to 0.

*Otherwise:*

Reserved, RAZ/WI.

**Accessing the OSDLR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSDLR_EL1</td>
<td>10</td>
<td>0001</td>
<td>000</td>
<td>100</td>
<td>0011</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RW EL1 n/a EL2 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDOSA == 1, then accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDOSA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.22 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

**Purpose**

Used for save/restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

**Configurations**

AArch64 System register OSDTRRX_EL1[31:0] is architecturally mapped to AArch32 System register DBGDTRRXext[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

OSDTRRX_EL1 is a 64-bit register.

**Field descriptions**

The OSDTRRX_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>63 32 31 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Update DTRRX without side-effect</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**Bits [31:0]**

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

**Accessing the OSDTRRX_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSDTRRX_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>010</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -; EL1: RW; EL2: n/a; EL3: RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of OSDTRRX_EL1 when the OS Lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
— If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.23  OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

**Purpose**

Used for save/restore of DBGDTRTX_EL0. It is a component of the Debug Communications Channel.

**Configurations**

AArch64 System register OSDTRTX_EL1[31:0] is architecturally mapped to AArch32 System register DBGDTRTXext[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

OSDTRTX_EL1 is a 64-bit register.

**Field descriptions**

The OSDTRTX_EL1 bit assignments are:

```
          63  32  31  0
  RES0   ??   ??   ??
            Return DTRTX without side-effect

Bits [63:32]
  Reserved, RES0.

Bits [31:0]
  Return DTRTX without side-effect.
  Reads of this register return the value in DTRTX and do not change TXfull.
  Writes of this register update the value in DTRTX and do not change TXfull.
  For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.
```

**Accessing the OSDTRTX_EL1**

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

```
<systemreg>  op0  CRn  op1  op2  CRm
OSDTRTX_EL1  10  0000  000  010  0011
```
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RW n/a EL2 RW EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of OSDTRTX_EL1 when the OS Lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.24 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

**Purpose**

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

**Configurations**

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSECCR[31:0].

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to External register EDECCR[31:0].

If OSLSR_EL1.OSLK == 0, then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

OSECCR_EL1 is a 64-bit register.

**Field descriptions**

The OSECCR_EL1 bit assignments are:

*When OSLSR.OSLK == 1:*

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EDECCR</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Reads or writes to this field are indirect accesses to EDECCR.

**Accessing the OSECCR_EL1**

This register can be written using MSR (register) with the following syntax:

`MSR <systemreg>, <Xt>`

This register can be read using MRS with the following syntax:

`MRS <Xt>, <systemreg>`

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSECCR_EL1</td>
<td>10</td>
<td>0000</td>
<td>000</td>
<td>010</td>
<td>0110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

```
<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
```

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDA == 1, then accesses at EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TDA == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.25 **OSLAR_EL1, OS Lock Access Register**

The OSLAR_EL1 characteristics are:

**Purpose**

Used to lock or unlock the OS Lock.

**Configurations**

AArch64 System register OSLAR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLAR[31:0].

AArch64 System register OSLAR_EL1[31:0] is architecturally mapped to External register OSLAR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

OSLAR_EL1 is a 64-bit register.

**Field descriptions**

The OSLAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>62-1</td>
<td>Reserved</td>
<td>Reserved</td>
</tr>
<tr>
<td>0</td>
<td>OSLK</td>
<td>On writes to OSLAR_EL1, bit[0] is copied to the OS Lock. Use OSLSR_EL1.OSLK to check the current status of the lock.</td>
</tr>
</tbody>
</table>

**Accessing the OSLAR_EL1**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSLAR_EL1</td>
<td>10</td>
<td>0001</td>
<td>000</td>
<td>100</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDOSA == 1, then write accesses at EL1 are trapped to EL2.

— If IsUsingAArch64(EL3) && MDCR_EL3.TDOSA == 1, then write accesses at EL1 or EL2 are trapped to EL3.
D12.3.26 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS Lock.

Configurations

AArch64 System register OSLSR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLSR[31:0].

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

OSLSR_EL1 is a 64-bit register.

Field descriptions

The OSLSR_EL1 bit assignments are:

$$
\begin{array}{cccccccc}
63 & 62 & 61 & 60 & 59 & 58 & 57 & 56 & 4 & 3 & 2 & 1 & 0 \\
| & | & | & | & | & | & | & | & | & | & \\
| & | & | & | & | & | & | & | & | & | \\
RES0 & OSLM[3,0] & OSLK & nTT & OSLM[3,0] \\
\end{array}
$$

Bits [63:4]

Reserved, RES0.

OSLM[3,0], bit [3]

OS lock model implemented. Bits [3] and [0] interpreted together identify the form of OS save and restore mechanism implemented.

- 0b00: OS Lock not implemented.
- 0b10: OS Lock implemented.

All other values are reserved. In an ARMv8 implementation the value 0b00 is not permitted.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status.

- 0b0: OS Lock unlocked.
- 0b1: OS Lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On a Cold reset, this field resets to 1.
OSLM[3,0], bit [0]

OS lock model implemented. Bits [3] and [0] interpreted together identify the form of OS save and restore mechanism implemented.

0b00  OS Lock not implemented.
0b10  OS Lock implemented.

All other values are reserved. In an ARMv8 implementation the value 0b00 is not permitted.

Accessing the OSLSR_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSLSR_EL1</td>
<td>10</td>
<td>0001</td>
<td>000</td>
<td>100</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: -  EL1: RO  EL2: n/a  EL3: RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TDOSA == 1, then read accesses at EL1 are trapped to EL2.
— If IsUsingAAArch64(EL3) && MDCR_EL3.TDOSA == 1, then read accesses at EL1 or EL2 are trapped to EL3.
D12.3.27 PMMIR_EL1, Performance Monitors Machine Identification Register

The PMMIR_EL1 characteristics are:

**Purpose**

Describes Performance Monitors parameters specific to the implementation to software.

**Configurations**

This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR_EL1 are UNDEFINED.

Configuration details:
- RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMMIR_EL1 is a 64-bit register.

**Field descriptions**

The PMMIR_EL1 bit assignments are:

- **Bits [63:8]**
  - Reserved, RES0.

- **SLOTS, bits [7:0]**
  - Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

**Accessing the PMMIR_EL1**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMMIR_EL1</td>
<td>11</td>
<td>1001</td>
<td>000</td>
<td>110</td>
<td>1110</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RO n/a RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && MDCR_EL2.TPM == 1, then accesses at EL1 are trapped to EL2.

— If HaveEL(EL3) && MDCR_EL3.TPM == 1, then accesses at EL1 or EL2 are trapped to EL3.
D12.3.28  SDER32_EL2, AArch32 Secure Debug Enable Register

The SDER32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register SDER from Secure EL2 and EL3 only.

**Configurations**

This register has no effect if EL2 is not enabled in the current Security state.

If EL1 is AArch64 only, this register is UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SDER32_EL2 is a 64-bit register.

**Field descriptions**

The SDER32_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit #</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-2</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>1</td>
<td>SUNIDEN, Secure User Non-Invasive Debug Enable:</td>
</tr>
<tr>
<td></td>
<td>0b0     Performance Monitors event counting prohibited in Secure EL0 unless allowed by MDCR_EL3.SPME or the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().</td>
</tr>
<tr>
<td></td>
<td>0b1     Performance Monitors event counting allowed in Secure EL0.</td>
</tr>
<tr>
<td>0</td>
<td>SUIDEN, Secure User Invasive Debug Enable:</td>
</tr>
<tr>
<td></td>
<td>0b0     Debug exceptions other than Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by MDCR_EL3.SPD32.</td>
</tr>
<tr>
<td></td>
<td>0b1     Debug exceptions from Secure EL0 are enabled.</td>
</tr>
</tbody>
</table>

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the SDER32_EL2**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDER32_EL2</td>
<td>11</td>
<td>0001</td>
<td>100</td>
<td>001</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>- - n/a RW</td>
</tr>
<tr>

<td>- - RW RW</td>
</tr>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 1 &amp;&amp; HCR_EL2.TGE == 1</td>
<td>- n/a RW RW</td>
</tr>
<tr>
<td>SCR_EL3.NS == 1 &amp;&amp; HCR_EL2.TGE == 0</td>
<td>- - - RW</td>
</tr>
<tr>
<td>SCR_EL3.NS == 1 &amp;&amp; HCR_EL2.TGE == 1</td>
<td>- n/a - RW</td>
</tr>
</tbody>
</table>
D12.3.29  SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

**Purpose**
Allow access to the AArch32 register SDER from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Configurations**
AArch64 System register SDER32_EL3[31:0] is architecturally mapped to AArch32 System register SDER[31:0].
If EL1 is AArch64 only, this register is UNDEFINED.
This register is in the Warm reset domain. On a Warm or Cold reset, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
SDER32_EL3 is a 64-bit register.

**Field descriptions**
The SDER32_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>62</td>
<td>SUNIDEN, bit [1]</td>
</tr>
<tr>
<td>61</td>
<td>Secure User Non-Invasive Debug Enable:</td>
</tr>
<tr>
<td>0</td>
<td>Performance Monitors event counting prohibited in Secure EL0 unless allowed by MDCR_EL3.SPME or the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().</td>
</tr>
<tr>
<td>1</td>
<td>Performance Monitors event counting allowed in Secure EL0.</td>
</tr>
<tr>
<td>60</td>
<td>SUIDEN, bit [0]</td>
</tr>
<tr>
<td>0</td>
<td>Secure User Invasive Debug Enable:</td>
</tr>
<tr>
<td>0</td>
<td>Debug exceptions other than Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by MDCR_EL3.SPD32.</td>
</tr>
<tr>
<td>1</td>
<td>Debug exceptions from Secure EL0 are enabled.</td>
</tr>
</tbody>
</table>

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the SDER32_EL3**
This register can be written using MSR (register) with the following syntax:

```assembly
MSR <systemreg>, <Xt>
```

This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDER_EL3</td>
<td>11</td>
<td>001</td>
<td>110</td>
<td>001</td>
<td>0001</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
D12.3.30 TRFCR_EL1, Trace Filter Control Register (EL1)

The TRFCR_EL1 characteristics are:

**Purpose**
Provides EL1 controls for Trace.

**Configurations**
AArch64 System register TRFCR_EL1[31:0] is architecturally mapped to AArch32 System register TRFCR[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR_EL1 are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
TRFCR_EL1 is a 64-bit register.

**Field descriptions**
The TRFCR_EL1 bit assignments are:

```
+-------------------+---+---+---+---+---+---+---+
|       63          | 7 | 6 | 5 | 4 | 2 | 1 | 0 |
| (RES0)            |   |   | TS|   |   |   |   |
| E0TRE             |   |   |   |   |   |   |   |
| E1TRE             |   |   |   |   |   |   |   |
```

**Bits [63:7]**
Reserved, RES0.

**TS, bits [6:5]**
Timestamp Control

- **0b01** Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2.
- **0b11** Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved

This field is ignored if any of the following are true:
- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and TRFCR_EL2.TS != 0b0.

**Bits [4:2]**
Reserved, RES0.

**E1TRE, bit [1]**
EL1 Trace Enable.

- **0b0** Trace is prohibited at EL1.
- **0b1** Trace is allowed at EL1.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, this field resets to 0.
E0TRE, bit [0]

EL0 Trace Enable.

0b0 Trace is prohibited at EL0.

0b1 Trace is allowed at EL0.

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE == 1.

On a Warm reset, this field resets to 0.

Accessing the TRFCR_EL1

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR_EL1</td>
<td>0001</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0010</td>
</tr>
<tr>
<td>TRFCR_EL12</td>
<td>0001</td>
<td>11</td>
<td>101</td>
<td>001</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR_EL1</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0: RW, EL1: n/a, EL2: RW, EL3: RW</td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.NV == 1 &amp;&amp; HCR_EL2.NV1 == 1 &amp;&amp; HCR_EL2.NV2 == 1 &amp;&amp; HCR_EL2.TGE == 0 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>

<td>Configuration</td>
<td>Accessibility</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.NV == 1 &amp; HCR_EL2.NV1 == 1 &amp; HCR_EL2.TGE == 0 &amp; HCR_EL2.E2H == 1 &amp;</td>
<td>TRFCR_EL2</td>
</tr>
<tr>
<td></td>
<td>SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL12</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>TRFCR_EL2</td>
</tr>
<tr>
<td></td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL12</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL12</td>
<td>(HCR_EL2.NV == 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL12</td>
<td>HCR_EL2.TGE == 1 &amp; HCR_EL2.E2H == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

TRFCR_EL12 is present only if HaveEL(EL2) && IsFeatureImplemented(ARMv8.1-VHE) is true. Otherwise, direct accesses to TRFCR_EL12 are UNDEFINED.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191*. Subject to the prioritization rules:

- If HaveEL(EL2) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAccessor(TRFCR_EL1), then accesses at EL1 are trapped to EL2.
- If HaveEL(EL3) && MDCR_EL2.TTRF == 1 && IsUsingAccessor(TRFCR_EL1) || IsUsingAccessor(TRFCR_EL12), then accesses at EL2 are trapped to EL3.
- If HaveEL(EL3) && MDCR_EL3.TTRF == 1 && IsUsingAccessor(TRFCR_EL1) || IsUsingAccessor(TRFCR_EL12), then accesses at EL1 are trapped to EL3.
- If (HCR_EL2.NV2 == 0 || HCR_EL2.NV1 == 1) && HaveEL(EL2) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && HCR_EL2.NV == 1 && (HCR_EL2.NV1 == 1 || HCR_EL2.NV2 == 0) && IsUsingAccessor(TRFCR_EL12), then accesses at EL1 are trapped to EL2.
D12.3.31 TRFCR_EL2, Trace Filter Control Register (EL2)

The TRFCR_EL2 characteristics are:

**Purpose**
Provides EL2 controls for Trace.

**Configurations**
AArch64 System register TRFCR_EL2[31:0] is architecturally mapped to AArch32 System register HTRFCR[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR_EL2 are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
TRFCR_EL2 is a 64-bit register.

**Field descriptions**
The TRFCR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>6-5</td>
<td>TS, Timestamp Control</td>
</tr>
<tr>
<td></td>
<td>Controls which timebase is used for trace timestamps.</td>
</tr>
<tr>
<td>0</td>
<td>Timestamp controlled by TRFCR_EL1.TS or TRFCR.TS.</td>
</tr>
<tr>
<td>0</td>
<td>Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2.</td>
</tr>
<tr>
<td>1</td>
<td>Physical timestamp. The traced timestamp is the physical counter value.</td>
</tr>
<tr>
<td>4</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>CONTEXTIDR_EL2 and VMID trace enable.</td>
</tr>
<tr>
<td>0</td>
<td>CONTEXTIDR_EL2 and VMID trace prohibited.</td>
</tr>
<tr>
<td>1</td>
<td>CONTEXTIDR_EL2 and VMID trace allowed.</td>
</tr>
</tbody>
</table>

This field is ignored if SelfHostedTraceEnabled() == FALSE.

On a Warm reset, this field resets to 0.
On a Warm reset, this field resets to 0.

Bit [2]

Reserved, RES0.

**E2TRE, bit [1]**

EL2 Trace Enable.

0b0 Trace is prohibited at EL2.

0b1 Trace is allowed at EL2.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, this field resets to 0.

**E0HTRE, bit [0]**

EL0 Trace Enable.

0b0 Trace is prohibited at EL0 when HCR_EL2.TGE == 1.

0b1 Trace is allowed at EL0 when HCR_EL2.TGE == 1.

This field is ignored if any of the following are true:

- **HCR_EL2.TGE == 0.**
- **SelfHostedTraceEnabled() == FALSE.**
- **EL2 is disabled in the current security state.**

On a Warm reset, this field resets to 0.

### Accessing the TRFCR_EL2

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>CRn</th>
<th>op0</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR_EL2</td>
<td>0001</td>
<td>11</td>
<td>100</td>
<td>001</td>
<td>0010</td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>0001</td>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0010</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR_EL2</td>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 - EL1, EL2 n/a EL3 RW</td>
</tr>
<tr>
<td>TRFCR_EL2</td>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>TRFCR_EL2</td>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>
If EL2 is not enabled, or if HCR_EL2.NV == 0, direct reads and writes using the register name TRFCR_EL2 at EL1 are UNDEFINED.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see Syncrhonous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If HaveEL(EL2) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAccessor(TRFCR_EL1), then accesses at EL1 are trapped to EL2.
- If HaveEL(EL3) && MDCR_EL3.TTRF == 1 && (IsUsingAccessor(TRFCR_EL2) || IsUsingAccessor(TRFCR_EL1)), then accesses at EL2 are trapped to EL3.
- If HaveEL(EL2) && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && HCR_EL2.NV == 1 && IsUsingAccessor(TRFCR_EL2), then accesses at EL1 are trapped to EL2.

<table>
<thead>
<tr>
<th>TRFCR_EL1</th>
<th>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</th>
<th>-</th>
<th>TRFCR_EL1</th>
<th>n/a</th>
<th>TRFCR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>n/a</td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>TRFCR_EL1</td>
</tr>
<tr>
<td>TRFCR_EL1</td>
<td>HCR_EL2.TGE == 1 &amp;&amp; HCR_EL2.E2H == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
<td>SCR_EL3.EEL2 == 1)</td>
<td>-</td>
<td>n/a</td>
</tr>
</tbody>
</table>
D12.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.
D12.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

**Purpose**
Determine the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

**Configurations**
AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch32 System register PMCCFILTR[31:0].

AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to External register PMCCFILTR_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
PMCCFILTR_EL0 is a 64-bit register.

**Field descriptions**
The PMCCFILTR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31</td>
<td>Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMCCFILTR_EL0.NSK bit. The possible values of this bit are: 0b0 Count cycles in EL1. 0b1 Do not count cycles in EL1. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMCCFILTR_EL0.NSU bit. The possible values of this bit are: 0b0 Count cycles in EL0. 0b1 Do not count cycles in EL0. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>29</td>
<td>Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.</td>
</tr>
</tbody>
</table>
If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Non-secure EL1 are counted.
Otherwise, cycles in Non-secure EL1 are not counted.
This field resets to an architecturally UNKNOWN value.

**NSU, bit [28]**
Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMCCFILTR_EL0.U bit, cycles in Non-secure EL0 are counted.
Otherwise, cycles in Non-secure EL0 are not counted.
This field resets to an architecturally UNKNOWN value.

**NSH, bit [27]**
EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0.
If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMCCFILTR_EL0.SH bit.
\[0b0\] Do not count cycles in EL2.
\[0b1\] Count cycles in EL2.
This field resets to an architecturally UNKNOWN value.

**M, bit [26]**
Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Secure EL3 are counted.
Otherwise, cycles in Secure EL3 are not counted.
Most applications can ignore this field and set its value to 0.

--- Note
This field is not visible in the AArch32 PMCCFILTR System register.

---
This field resets to an architecturally UNKNOWN value.

**Bit [25]**
Reserved, RES0.

**SH, bit [24]**

*When ARMv8.4-SecEL2 is implemented:*
Secure EL2 filtering.
If the value of this bit is not equal to the value of the PMCCFILTR_EL0.NSH bit, cycles in Secure EL2 are counted.
Otherwise, cycles in Secure EL2 are not counted.
If Secure EL2 is not implemented or is disabled, this field is RES0.

--- Note
This field is not visible in the AArch32 PMCCFILTR System register.

---
This field resets to an architecturally UNKNOWN value.

*Otherwise:*
Reserved, RES0.
Bits [23:0]
Reserved, RES0.

**Accessing the PMCCFILTR_EL0**
This register can be written using MSR (register) with the following syntax:
MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:
MRS <Xt>, <systemreg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMCCFILTR_EL0</td>
<td>11</td>
<td>1110</td>
<td>011</td>
<td>111</td>
<td>111</td>
</tr>
</tbody>
</table>

PMCCFILTR_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEI set to 0b11111.

**Accessibility**
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RW, EL1 RW, EL2 n/a, EL3 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

— If PMUSERENR_EL0.EN == 0 && (HCR_EL2.TGE == 0 && (SCR_EL3.NS == 0 || SCR_EL3.EEL2 == 0)), then accesses at EL0 are trapped to EL1.
— If PMUSERENR_EL0.EN == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then accesses at EL0 or EL1 are trapped to EL2.
— If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TPM == 1, then accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter on page D6-2539* for more information. PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

**Configurations**

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to AArch32 System register PMCCNTR[63:0].

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to External register PMCCNTR_EL0[63:0].

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is **CONSTRAINED UNPREDICTABLE** whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCCNTR_EL0 is a 64-bit register.

**Field descriptions**

The PMCCNTR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>CCNT, bits [63:0]</td>
</tr>
</tbody>
</table>

CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMCCNTR_EL0**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMCCNTR_EL0</td>
<td>11</td>
<td>1001</td>
<td>011</td>
<td>000</td>
<td>1101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

- If PMUSERENR_EL0.CR == 0 && PMUSERENR_EL0.EN == 0 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then read accesses at EL0 are trapped to EL1.
- If PMUSERENR_EL0.CR == 0 && PMUSERENR_EL0.EN == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.
- If PMUSERENR_EL0.EN == 0 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then write accesses at EL0 are trapped to EL1.
- If PMUSERENR_EL0.EN == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then write accesses at EL0 are trapped to EL2.
- If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TPM == 1, then accesses at EL0 or EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) && MDCR_EL3.TPM == 1, then accesses at EL0, EL1 or EL2 are trapped to EL3.
D12.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0000 to 0x001F and 0x4000 to 0x401F. When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

--- Note ---

ARM recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see *The PMU event number space and common events* on page D6-2557.

**Configurations**

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID2[31:0].

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to External register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to External register PMCEID2[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCEID0_EL0 is a 64-bit register.

**Field descriptions**

The PMCEID0_EL0 bit assignments are:

```
63 32 31 0
IDhi<n>, bit [n+32] ID<n>, bit [n]
```

**IDhi<n>, bit [n+32], for n = 0 to 31**

*When ARMv8.1-PMU is implemented:*

IDhi[n] corresponds to common event (0x4000 + n).

For each bit:

| 0b0 | The common event is not implemented, or not counted. |
| 0b1 | The common event is implemented. |

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note ---

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.
Otherwise:
Reserved, RES0.

ID<\textit{n}>, bit [\textit{n}], for \textit{n} = 0 to 31
ID[n] corresponds to common event \textit{n}.
For each bit:
\begin{itemize}
  \item 0b0 The common event is not implemented, or not counted.
  \item 0b1 The common event is implemented.
\end{itemize}
A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

\begin{note}
Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<\textit{n}>_EL0 registers of that earlier version of the PMU architecture.
\end{note}

Accessing the PMCEID0_EL0
This register can be read using MRS with the following syntax:

MRS <\textit{Xt}>, <\textit{systemreg}>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMCEID0_EL0</td>
<td>11</td>
<td>1001</td>
<td>011</td>
<td>110</td>
<td>110</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see \textit{Synchronous exception prioritization for exceptions taken to AArch64 state} on page D1-2191. Subject to the prioritization rules:

\begin{itemize}
  \item If PMUSERENR_EL0.EN == 0 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then read accesses at EL0 are trapped to EL1.
  \item If PMUSERENR_EL0.EN == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.
  \item If (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TPM == 1, then read accesses at EL0 or EL1 are trapped to EL2.
  \item If IsUsingAArch64(EL3) && MDCR_EL3.TPM == 1, then read accesses at EL0 EL1 or EL2 are trapped to EL3.
\end{itemize}
D12.4.4 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0020 to 0x003F and 0x4020 to 0x403F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

ARM recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see The PMU event number space and common events on page D6-2557.

Configurations

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID3[31:0].

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to External register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to External register PMCEID3[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID1_EL0 is a 64-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:

From ARMv8.1:

IDhi[n], bit [n+32] corresponds to common event (0x4020 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.
**Otherwise:**
Reserved, RES0.

**ID<n>, bit [n], for n = 0 to 31**
ID[n] corresponds to common event (0x0020 + n).

For each bit:
- 0b0: The common event is not implemented, or not counted.
- 0b1: The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- **Note** ---
Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

**Accessing the PMCEID1_EL0**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMCEID1_EL0</td>
<td>11</td>
<td>1001</td>
<td>011</td>
<td>111</td>
<td>1100</td>
</tr>
</tbody>
</table>

**Accessibility**
The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp; SCR_EL3.EEL2 == 0</td>
<td>RO n/a RO RO</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2191. Subject to the prioritization rules:

- If PMUSERENR_EL0.EN == 0 & (HCR_EL2.TGE == 0 || SCR_EL3.NS == 0 & SCR_EL3.EEL2 == 0), then read accesses at EL0 are trapped to EL1.
- If PMUSERENR_EL0.EN == 0 & HCR_EL2.TGE == 1 & (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then read accesses at EL0 are trapped to EL2.
- If SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1 & IsUsingAArch64(EL2) & MDCR_EL2.TPM == 1, then read accesses at EL0 or EL1 are trapped to EL2.
- If IsUsingAArch64(EL3) & MDCR_EL3.TPM == 1, then read accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

**Purpose**
Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

**Configurations**
AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENCLR[31:0].
AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to External register PMCNTENCLR_EL0[31:0].
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
PMCNTENCLR_EL0 is a 64-bit register.

**Field descriptions**
The PMCNTENCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31</td>
<td>PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:</td>
</tr>
<tr>
<td>0b0</td>
<td>When read, means the cycle counter is disabled. When written, has no effect.</td>
</tr>
<tr>
<td>0b1</td>
<td>When read, means the cycle counter is enabled. When written, disables the cycle counter.</td>
</tr>
<tr>
<td>30-0</td>
<td>PMEVCNTR&lt;n&gt;_EL0 disable bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
</tbody>
</table>

Bits [63:32] Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:
0b0 When read, means the cycle counter is disabled. When written, has no effect.
0b1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for PMEVCNTR<n>_EL0.

Bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N. Possible values of each bit are:
0b0 When read, means that PMEVCNTR<n>_EL0 is disabled. When written, has no effect.
0b1 When read, means that PMEVCNTR<n>_EL0 is enabled. When written, disables PMEVCNTR<n>_EL0.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMCNTENCLR_EL0**

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>
This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;systemreg&gt;</th>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMCNTENCLR_EL0</td>
<td>11</td>
<td>1001</td>
<td>011</td>
<td>010</td>
<td>1100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.NS == 0 &amp;&amp; SCR_EL3.EEL2 == 0</td>
<td>EL0 RW</td>
</tr>
<tr>
<td></td>
<td>EL1 RW</td>
</tr>
<tr>
<td></td>
<td>EL2 n/a</td>
</tr>
<tr>
<td></td>
<td>EL3 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 0 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL1 RW</td>
</tr>
<tr>
<td></td>
<td>EL2 RW</td>
</tr>
<tr>
<td></td>
<td>EL3 RW</td>
</tr>
<tr>
<td>HCR_EL2.TGE == 1 &amp;&amp; (SCR_EL3.NS == 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL1 n/a</td>
</tr>
<tr>
<td></td>
<td>EL2 RW</td>
</tr>
<tr>
<td></td>
<td>EL3 RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191. Subject to the prioritization rules:

— If PMUSERENR_EL0.EN == 0 && (HCR_EL2.TGE == 0 || (SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0)), then accesses at EL0 are trapped to EL1.

— If PMUSERENR_EL0.EN == 0 && HCR_EL2.TGE == 1 && (SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1), then accesses at EL0 are trapped to EL2.

— If SCR_EL3.NS == 1 || SCR_EL3.EEL2 == 1) && IsUsingAArch64(EL2) && MDCR_EL2.TPM == 1, then accesses at EL0 EL1 or EL2 are trapped to EL3.

— If IsUsingAArch64(EL3) && MDCR_EL3.TPM == 1, then accesses at EL0 EL1 or EL2 are trapped to EL3.
D12.4.6  PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<->. Reading this register shows which counters are enabled.

**Configurations**

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENSET[31:0].

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to External register PMCNTENSET_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCNTENSET_EL0 is a 64-bit register.

**Field descriptions**

The PMCNTENSET_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:32]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>C, bit [31]</td>
<td>PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>0b0 When read, means the cycle counter is disabled. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td>0b1 When read, means the cycle counter is enabled. When written, enables the cycle counter.</td>
</tr>
<tr>
<td></td>
