For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] EOR shifted;
  PSTATE.N = result<31>;
  PSTATE.Z = IsZeroBit(result);
  PSTATE.C = carry;
  // PSTATE.V unchanged

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.257  TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

```
[31  28|27  26  25  24|23  22  21  20|19  16|15  14  13  12|11  8 | 7 | 6 | 5 | 4 | 3 | 0 |

cond
```

A1 variant

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

*Decode for this encoding*

```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

*Notes for all encodings*

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

*Assembler symbols*

```
<
> See Standard assembler syntax fields on page F2-3654.
<
> See Standard assembler syntax fields on page F2-3654.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL  when type = 00
- LSR  when type = 01
- ASR  when type = 10
- ROR  when type = 11

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

*Operation*

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  (shifted, carry) = Shift_CCR[m], shift_t, shift_n, PSTATE.C);
  result = R[n] EOR shifted;
  PSTATE.N = result<31>;
  PSTATE.Z = IsZeroBit(result);
  PSTATE.C = carry;
  // PSTATE.V unchanged
```
Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.258   TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If the Self-Hosted Trace Extension is not implemented, this instruction executes as a NOP.

A1

ARMv8.4

```
|31 28 26 25 24 23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 8 |7 6 5 4 |3 2 1 0 |
|-------------------------------|
|   !=1111   0 0 1 1 0 |0 1 0 0 0 0 |0 |0 |1 |1 |0 |0 |0 0 1 0 |
| cond                                |
```

**A1 variant**

TSB{<c>}{<q>} CSYNC

**Decode for this encoding**

\[
\text{if } \neg \text{HaveSelfHostedTrace()} \text{ then EndOfInstruction(); // Instruction executes as NOP}
\]

\[
\text{if } \text{cond} \neq '1110' \text{ then UNPREDICTABLE; // ESB must be encoded with AL condition}
\]

**CONSTRANGED UNPREDICTABLE behavior**

If \text{cond} \neq '1110', then one of the following behaviors must occur:

- The instruction is **undefined**.
- The instruction executes as **NOP**.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

ARMv8.4

```
|15 14 13 12|11 10 9 8 |7 6 5 4 |3 2 1 0 |
|-------------------------------|
|   1 1 1 1 0 0 1 1 0 1 0 |0 |1 |1 |0 |0 |0 0 0 0 1 0 |
```

**T1 variant**

TSB{<c>}{<q>} CSYNC

**Decode for this encoding**

\[
\text{if } \neg \text{HaveSelfHostedTrace()} \text{ then EndOfInstruction(); // Instruction executes as NOP}
\]

\[
\text{if } \text{InITBlock()} \text{ then UNPREDICTABLE;}
\]

**CONSTRANGED UNPREDICTABLE behavior**

If \text{InITBlock}(), then one of the following behaviors must occur:

- The instruction is **undefined**.
- The instruction executes as **NOP**.
- The instruction executes unconditionally.
• The instruction executes conditionally.

**Assembler symbols**

<

See *Standard assembler syntax fields on page F2-3654*.

≤

See *Standard assembler syntax fields on page F2-3654*.

**Operation for all encodings**

if `ConditionPassed()` then
  EncodingSpecificOperations();
  TraceSynchronizationBarrier();
F5.1.259   TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

PSTATE.GE<3> = if sum4 >= 0x100 then '1' else '0';

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.264   UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one
unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination
register. It sets PSTATE.GE according to the results.

Assembler symbols

- **<c>** See Standard assembler syntax fields on page F2-3654.
- **<q>** See Standard assembler syntax fields on page F2-3654.
- **<Rd>** Is the general-purpose destination register, encoded in the "Rd" field.
- **<Rn>** Is the general-purpose source register, encoded in the "Rn" field.
- **<lsb>** For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
  For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
- **<width>** Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.
Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  msbit = lsbite + widthminus1;
  if msbit <= 31 then
    R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
  else
    UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If msbit > 31, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.266  UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

• With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
• In the A32 instruction set, UDF is not conditional.

// imm32 is for assembly and disassembly only, and is ignored by hardware.
Assembler symbols

For encoding A1: see *Standard assembler syntax fields on page F2-3654.* <> must be AL or omitted.

For encoding T1 and T2: see *Standard assembler syntax fields on page F2-3654.* ARM deprecates using any <> value other than AL.

See *Standard assembler syntax fields on page F2-3654.*

For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.

For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  UNDEFINED;
UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected. See Divide instructions on page F1-3623 for more information about this instruction.

<Rd>

Is the general-purpose destination register, encoded in the "Rd" field.

<Rn>

Is the first general-purpose source register, encoded in the "Rn" field.

<Rm>

Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
sum = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
R[d]<15:0> = diff<16:1>;
R[d]<31:16> = sum<16:1>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.271 UHSAX

Unsigned Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, halves the results, and writes the results to the destination register.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.285   USAT

Unsigned Saturate saturates an optionally-shifted signed value to a selected unsigned range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the bit position for saturation, in the range 0 to 31, encoded in the "sat_imm" field.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<amount> For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.
For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.
For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
### USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

**A1**

\end{align*}
\]

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.288  USUB16

Unsigned Subtract 16 performs two 16-bit unsigned integer subtractions, and writes the results to the destination register. It sets PSTATE.GE according to the results of the subtractions.

F5.1.296   WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any
PE in the multiprocessor system. For more information, see Wait For Event and Send Event on page G1-5300.

As described in Wait For Event and Send Event on page G1-5300, the execution of a WFE instruction that would
otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-5317.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-5333.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on
  page G1-5344.

\end{verbatim}
F5.1.298    YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see The Yield instruction on page F1-3629.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Yield();
F5.2 Encoding and use of banked register transfer instructions

Software executing at EL1 or higher can use the MRS (banked register) and MSR (banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- Register arguments in the banked register transfer instructions.
- Usage restrictions on the banked register transfer instructions on page F5-4515.
- Encoding the register argument in the banked register transfer instructions on page F5-4516.
- Pseudocode support for the banked register transfer instructions on page F5-4517.

For descriptions of the instructions see MRS (Banked register) on page F5-4098 and MSR (Banked register) on page F5-4102.

F5.2.1 Register arguments in the banked register transfer instructions

Figure F5-1 shows the banked general-purpose registers and Special-purpose registers:

![Figure F5-1 Banking of general-purpose and Special-purpose registers](image)

For the general-purpose registers, if no other register is shown, the current mode register is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

_____ Note _____

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (banked register) and MSR (banked register) instructions to access some SPSRs, as described in Usage restrictions on the banked register transfer instructions on page F5-4515.
- General-purpose registers R0-R7, that are not banked, cannot be accessed using the MRS (banked register) and MSR (banked register) instructions.
- In addition to the registers shown in Figure F5-1, the DLR and DSPSR are AArch32 System registers that map onto the AArch64 Special-purpose registers DLR_EL0 and DSPSR_EL0. However, DLR and DSPSR are not accessible using the MRS (banked register) and MSR (banked register) instructions.

Software using an MRS (banked register) or MSR (banked register) instruction specifies one of these registers using a name shown in Figure F5-1, or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12 Each of these registers has two banked copies, _usr and _fiq, for example R8_usr and R8_fiq.
SP

There is a banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.

LR

There is a banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.

SPSR

There is a banked copy of SPSR for every mode except System mode and User mode.

ELR_hyp

Except for the operations provided by MRS (banked register) and MSR (banked register), ELR_hyp is accessible only from Hyp mode. It is not banked.

**F5.2.2 Usage restrictions on the banked register transfer instructions**

MRS (banked register) and MSR (banked register) instructions are CONSTRAINED UNPREDICTABLE if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a banked register that is not implemented, or that either:
  - Is not accessible from the current Privilege level and Security state.
  - Can be accessed from the current mode by using a different instruction.

*MRS (banked register) and MSR (banked register)* on page K1-7216 describes the permitted CONSTRAINED UNPREDICTABLE behavior.

An MRS (banked register) instruction or an MSR (banked register) instruction executed:

- At Non-secure EL1 cannot access any Hyp mode banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp banked registers.

This means that the banked registers that MRS (banked register) and MSR (banked register) instructions cannot access are:

**From Monitor mode**

- The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

**From Hyp mode**

- The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

---

**Note**

MRS (banked register) and MSR (banked register) instructions can access the current mode register ELR_hyp.

---

**From FIQ mode**

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

**From System mode**

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

**From Supervisor mode, Abort mode, Undefined mode, and IRQ mode**

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.
F5.2 Encoding and use of banked register transfer instructions

If EL3 is using AArch64, all MRS (banked register) and MSR (banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.

For more information, see:
- Encoding the register argument in the banked register transfer instructions.
- Pseudocode support for the banked register transfer instructions on page F5-4517.
- MRS (Banked register) on page F5-4098.
- MSR (Banked register) on page F5-4102.

Note

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

F5.2.3 Encoding the register argument in the banked register transfer instructions

The MRS (banked register) and MSR (banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a banked copy of the SPSR, and Table F5-1 shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

When the R bit is set to 1, the argument is a banked copy of the SPSR, and Table F5-2 shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

### Pseudocode support for the banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRaccessValid()` check the validity of MRS (banked register) and MSR (banked register) accesses. That is, they filter the accesses that are CONSTRAINED UNPREDICTABLE either because:

- They attempt to access a register that *Usage restrictions on the banked register transfer instructions on page F5-4515* shows is not accessible.

- They use an SYSm<4:0> encoding that *Encoding the register argument in the banked register transfer instructions on page F5-4516* shows as CONSTRAINED UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and `SPSRaccessValid()` applies to accesses to the SPSRs.

F5 T32 and A32 Base Instruction Set Instruction Descriptions
F5.2 Encoding and use of banked register transfer instructions
Chapter F6
T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• Alphabetical list of Advanced SIMD and floating-point instructions on page F6-4520.

Note

Some headings in this chapter use the term floating-point register. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.
F6.1 Alphabetical list of Advanced SIMD and floating-point instructions

This section lists every Advanced SIMD and floating-point instruction in the T32 and A32 instruction sets. For details of the format used see Format of instruction descriptions on page F2-3650.

This section is formatted so that each instruction description starts on a new page.
F6.1.1 AESD

AES single round decryption.

A1

```

d = UInt(D:Vd); m = UInt(M:Vm);

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

<dt> Is the data type, encoded in the "size" field. It can have the following values:

- 8 when size = 00

The following encodings are reserved:

- size = 01.
- size = 1x.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    op1 = Q[d>>1]; op2 = Q[m>>1];
    Q[d>>1] = AESInvSubBytes(AESInvShiftRows(op1 EOR op2));

Operational information

If CPSR.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.2   AESE

AES single round encryption.

d = UInt(D:Vd); m = UInt(M:Vm);

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<dt> Is the data type, encoded in the "size" field. It can have the following values:

8  when size = 00

The following encodings are reserved:

•  size = 01.
•  size = 1x.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q[d>>1] = AESMixColumns(Q[m>>1]);

Operational information

If CPSR.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.5   FLDM*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see "Enabling Advanced SIMD and floating-point support on page G1-5308."

A1

[31 28 27 26 25 24 23 22 21 20 19 16 15 12 11 10 9 8 7 | 1 0 ]
| !=1111 | 1 1 0 | P U D W 1 | Rn | Vd 1 0 1 1 | imm8<7:1> | 1 |
| cond | imm8<0> |

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE "VLDI";
if P == '1' && W == '0' then UNDEFINED;
// Remaining combinations are P U W = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<8:6> == '1' && (d+regs) > 16 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.
T1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE "VLDR";
if P == U && W == '1' then UNDEFINED;

single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Related encodings: See Advanced SIMD and floating-point 64-bit move on page F3-3717 for the T32 instruction set, or Advanced SIMD and floating-point 64-bit move on page F4-3788 for the A32 instruction set.

Assembler symbols

See Standard assembler syntax fields on page F2-3654.
<Rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.

\[\text{!} \] Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEncabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
F6.1.6   FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

Decrement Before variant

Applies when \( P = 1 \) && \( U = 0 \) && \( W = 1 \).

\[
\text{FSTMDBX\{<c>\}{<q>} <Rn>!, <dreglist>}
\]

Increment After variant

Applies when \( P = 0 \) && \( U = 1 \).

\[
\text{FSTMIAX\{<c>\}{<q>} <Rn>{!}, <dreglist>}
\]

Decode for all variants of this encoding

if \( P = '0' \) && \( U = '0' \) && \( W = '0' \) then SEE "Related encodings";
if \( P = '1' \) && \( W = '0' \) then SEE "VSTR";
if \( P = U = W = 1 \) then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);

- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If \( \text{regs} > 16 \land (\text{d+regs}) > 16 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Related encodings: See Advanced SIMD and floating-point 64-bit move on page F3-3717 for the T32 instruction set, or Advanced SIMD and floating-point 64-bit move on page F4-3788 for the A32 instruction set.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-3654.
\(<aq>\) See Standard assembler syntax fields on page F2-3654.
<Rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecated use of the PC.

! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
  address = if add then R[n] else R[n]-imm32;
  for r = 0 to regs-1
    if single_regs then
      MemA[address,4] = S[d+r];  address = address+4;
    else
      // Store as two word-aligned words in the correct order for current endianness.
      MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
      MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
      address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<dt>
Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- U8 when U = 1, size = 00
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as Qd*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as Qn*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as Qm*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[D[d>>1],e,2*esize] = absdiff<2*esize-1:0>;
            else
                Elem[D[d+r],e,esize] = absdiff<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.21 VABDL (integer)

Vector Absolute Difference Long (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand elements are all integers of the same length, and the result elements are double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

                    result = Abs(SInt(Elem[D[m+r],e,esize]));
                    Elem[D[d+r],e,esize] = result<esize-1:0>;
                end
            end
        end
    else // VFP instruction
        case esize of
            when 16 S[d] = Zeros(16) : FPAbs(S[m]<15:0>);
            when 32 S[d] = FPAbs(S[m]);
            when 64 D[d] = FPAbs(D[m]);
        end
end
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.23 VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instruction VACLE. The pseudo-instruction is never the preferred disassembly.

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.24  VACLE

Vector Absolute Compare Less Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VACGE instruction. This means that:

- The encodings in this description are named to match the encodings of VACGE.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VACGE gives the operational pseudocode for this instruction.

**A1**

For 64-bit SIMD vector variant:

Applies when \( Q = 0 \).

\[
\text{VACLE}\{\langle c\rangle\}{\langle q\rangle}.<dt> \{<Dd>, \}<Dm>, \<Dn>
\]

is equivalent to

\[
\text{VACGE}\{\langle c\rangle\}{\langle q\rangle}.<dt> <Dd>, <Dm>, <Dn>
\]

and is never the preferred disassembly.

**128-bit SIMD vector variant**

Applies when \( Q = 1 \).

\[
\text{VACLE}\{\langle c\rangle\}{\langle q\rangle}.<dt> \{<Qd>, \}<Qm>, \<Qn>
\]

is equivalent to

\[
\text{VACGE}\{\langle c\rangle\}{\langle q\rangle}.<dt> <Qd>, <Qm>, <Qn>
\]

and is never the preferred disassembly.

**T1**

For 64-bit SIMD vector variant:

Applies when \( Q = 0 \).

\[
\text{VACLE}\{\langle c\rangle\}{\langle q\rangle}.<dt> \{<Dd>, \}<Dm>, \<Dn>
\]

is equivalent to

\[
\text{VACGE}\{\langle c\rangle\}{\langle q\rangle}.<dt> <Dd>, <Dm>, <Dn>
\]

and is never the preferred disassembly.
**128-bit SIMD vector variant**

Applies when \( Q = 1 \).

\[
\text{VACLE\{c\}\{q\}\{dt\} \{q_d\}, \{q_m\}, \{q_n\}}
\]

is equivalent to

\[
\text{VACGE\{c\}\{q\}\{dt\} \{q_d\}, \{q_m\}, \{q_n\}}
\]

and is never the preferred disassembly.

**Assembler symbols**

- \( <D_m> \) is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- \( <D_n> \) is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- \( <Q_m> \) is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \( <Q_m>*2 \).
- \( <Q_n> \) is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \( <Q_n>*2 \).
- \( <c> \) is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \( <Q_d>*2 \).
- \( <c> \) for encoding A1: see *Standard assembler syntax fields on page F2-3654*. This encoding must be unconditional.
- \( <c> \) for encoding T1: see *Standard assembler syntax fields on page F2-3654*.
- \( <D_d> \) is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- \( <D_d> \) is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

**Operation for all encodings**

The description of VACGE gives the operational pseudocode for this instruction.
F6.1.25 VACGT

Vector Absolute Compare Greater Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instruction VACL. The pseudo-instruction is never the preferred disassembly.

CONstrained UNPredictable behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<dt>
Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
F32 when sz = 0
F16 when sz = 1

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = FPAbs(Elem[D[n+r],e,esize]);  op2 = FPAbs(Elem[D[m+r],e,esize]);
      if or_equal then
        test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());
      else
        test_passed = FPCompareGT(op1, op2, StandardFPSCRValue());
      Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.26 VACLT

Vector Absolute Compare Less Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VACGT instruction. This means that:

- The encodings in this description are named to match the encodings of VACGT.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VACGT gives the operational pseudocode for this instruction.

Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:

- I8 when size = 00
- I16 when size = 01
- I32 when size = 10
- I64 when size = 11

<qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.

<qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <qn>*2.

<qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.

<dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            <dd>[r,e,esize] = <dn>[r,e,esize] + <dm>[r,e,esize];

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see VRADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

  - The values of the NZCV flags.
**F6.1.32 VAND (immediate)**

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VBIC (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VBIC (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VBIC (immediate) gives the operational pseudocode for this instruction.

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.

Assembler symbols

For encoding A1 and A2: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1 and T2: see Standard assembler syntax fields on page F2-3654.

<q>  
See Standard assembler syntax fields on page F2-3654.

<Qd>  
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd>  
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm>  
Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-3671.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.35 VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

            when VBitOps_VBSL  D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]));
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.39  VCADD

Vector Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

F6.1.40  VCEQ (immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.43  VCGE (register)

Vector Compare Greater Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers, unsigned integers, or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instruction VCLE (register). The pseudo-instruction is never the preferred disassembly.

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
type = VCGEtype_fp;
case sz of

when '0' esize = 32; elements = 2;
when '1' esize = 16; elements = 4;
\[d = \text{UInt}(\text{D}:\text{Vd}); \quad n = \text{UInt}(\text{N}:\text{Vn}); \quad m = \text{UInt}(\text{M}:\text{Vm}); \quad \text{regs} = \text{if } Q == '0' \text{ then } 1 \text{ else } 2;\]

**CONSTRAINED UNPREDICTABLE behavior**

If \(sz == '1' \& \& \text{InITBlock()}\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

- For encoding A1 and A2: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  - For encoding T1 and T2: see Standard assembler syntax fields on page F2-3654.
- See Standard assembler syntax fields on page F2-3654.

- For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
  - S8 when \(U = 0, size = 00\)
  - S16 when \(U = 0, size = 01\)
  - S32 when \(U = 0, size = 10\)
  - U8 when \(U = 1, size = 00\)
  - U16 when \(U = 1, size = 01\)
  - U32 when \(U = 1, size = 10\)

  For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
  - F32 when \(sz = 0\)
  - F16 when \(sz = 1\)

- \(<\text{Qd}>\) Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<\text{Qd}>*2\).
- \(<\text{Qn}>\) Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<\text{Qn}>*2\).
- \(<\text{Qm}>\) Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<\text{Qm}>*2\).
- \(<\text{Dd}>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- \(<\text{Dn}>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- \(<\text{Dm}>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
**\[\text{operation} = \text{if } \text{ConditionPassed()} \text{ then} \text{EncodingSpecificOperations()}; \text{CheckAdvSIMDEnabled();} \text{for } r = 0 \text{ to } \text{regs}-1 \text{ for } e = 0 \text{ to } \text{elements}-1 \text{ op1} = \text{Elem}[\text{D}[n+r],e,\text{esize}]; \text{ op2} = \text{Elem}[\text{D}[m+r],e,\text{esize}]; \text{ case type of} \text{ when VCGEtype_signed} \text{ test_passed} = (\text{SInt}(\text{op1}) >= \text{SInt}(\text{op2}));**
```

Armed with this detailed description, you can now implement the operations described by the code above.
when VCGEtype_unsigned  test_passed = (UInt(op1) >= UInt(op2));
when VCGEtype_fp        test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());
Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.44  VCGT (Immediate #0)

Vector Compare Greater Than Zero takes each element in a vector, and compares it with zero. If it is greater than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

F6.1.47   VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VCGE (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGE (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGE (register) gives the operational pseudocode for this instruction.

**Operation for all encodings**

The description of VCGE (register) gives the operational pseudocode for this instruction.
F6.1.48   VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same
as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include
the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.49   **VCLT (immediate #0)**

Vector Compare Less Than Zero takes each element in a vector, and compares it with zero. If it is less than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

            test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);

Operational information
If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.50 VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VCGT (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGT (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGT (register) gives the operational pseudocode for this instruction.

<qm>  Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.
<dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<dm>  Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = CountLeadingZeroBits(Elem[D[m+r],e,esize]<esize-1:0>);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.52 VCMLA

Vector Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on the
corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is
  rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a
    rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was
    a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination
  register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate
rounding.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

        Elem[D[d+r],e*2+1,esize] = result2;
**F6.1.54 VCMP**

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the PSTATE.{N, Z, C, V} Condition flags by a subsequent VMRS instruction.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

VOPPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            nzcv = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            nzcv = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
    FPSCR.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
**F6.1.55 VCMPE**

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the PSTATE, {N, Z, C, V} Condition flags by a subsequent VMRS instruction.

It raises an Invalid Operation exception if either operand is any type of NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

**A1**

```
![instruction encoding]
```

**Half-precision scalar variant**

Applies when size == 01.

if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
quiet_nan_exc = (E == '1'); with_zero = TRUE;
case size of
  when '01' esize = 16; d = UInt(Vd:D); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);
```

**CONSTRANGED UNPREDICTABLE behavior**

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-3654.
\(<q>\) See Standard assembler syntax fields on page F2-3654.
\(<Sd>\) Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
\(<Sm>\) Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
\(<Dm>\) Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of \(<, ==, >\) or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

VÖPE raises anInvalid Operation exception if either operand is any type ofNaN, and is suitable for testing for \(<, <=, >, >=\), and other predicates that raise an exception when the operands are unordered.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    bits(4) nzcv;
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            nzcv = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];

      Elem[D[e],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());
F6.1.59 VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

### F6.1.61 VCVT (integer to floating-point, floating-point)

Convert integer to floating-point converts a 32-bit integer to floating-point using the rounding mode specified by the FPSCR, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be undefined, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

**Assembler symbols**

<c> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
   For encoding T1: see Standard assembler syntax fields on page F2-3654.
<br> See Standard assembler syntax fields on page F2-3654.
<dt1> Is the data type for the elements of the destination vector, encoded in the "op:U" field. It can have the following values:
   F16 when op = 00, U = x
   S16 when op = 01, U = 0
   U16 when op = 01, U = 1
   F32 when op = 10, U = x
   S32 when op = 11, U = 0
   U32 when op = 11, U = 1
<br> Is the data type for the elements of the source vector, encoded in the "op:U" field. It can have the following values:
   S16 when op = 00, U = 0
   U16 when op = 00, U = 1
   F16 when op = 01, U = x
   S32 when op = 10, U = 0
   U32 when op = 10, U = 1
   F32 when op = 11, U = x
<br> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<br> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<br> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<br> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<fbits> The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- \((64 - \text{<fbits>})\) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see VCVT (between floating-point and integer, Advanced SIMD).

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_fixed then
                result = FPToFixed(op1, frac_bits, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```
**F6.1.63 VCVT (between floating-point and fixed-point, floating-point)**

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

  when '01' fp_size = 16; d = UInt(Vd:D);
  when '10' fp_size = 32; d = UInt(Vd:D);
  when '11' fp_size = 64; d = UInt(D:Vd);

if frac_bits < 0 then UNPREDICTABLE;

CONSTRUED UNPREDICTABLE behavior

If frac_bits < 0, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINTE UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VCVT (between floating-point and fixed-point) on page K1-7209.

Assembler symbols

<><> See Standard assembler syntax fields on page F2-3654.
<><> See Standard assembler syntax fields on page F2-3654.
<dt> Is the data type for the fixed-point number, encoded in the "U:sx" field. It can have the following values:
  S16  when U = 0, sx = 0
  S32  when U = 0, sx = 1
  U16  when U = 1, sx = 0
  U32  when U = 1, sx = 1
<5dm> Is the 32-bit name of the SIMD&FP destination and source register, encoded in the "Vd:D" field.
<6dm> Is the 64-bit name of the SIMD&FP destination and source register, encoded in the "D:Vd" field.
<fbits> The number of fraction bits in the fixed-point number:
  • If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]
  • If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i].

F6.1.64  VCVTA (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest with Ties to Away converts each element in a vector from floating-point to integer using the Round to Nearest with Ties to Away rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are 32-bit integers. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPACR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

F6.1.74   **VCVTT**

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F2-3654. ARM strongly recommends that any VDUP instruction is unconditional, see Conditional execution on page F2-3655.

<
See Standard assembler syntax fields on page F2-3654.

<size>
The data size for the elements of the destination vector. It must be one of:
8
   Encoded as [b, e] = 0b10.
16
   Encoded as [b, e] = 0b01.
32
   Encoded as [b, e] = 0b00.

<Qd>
The destination vector for a quadword operation.

<Dd>
The destination vector for a doubleword operation.

<Rt>
The ARM source register.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   scalar = R[t]<esize-1:0>;
   for r = 0 to regs-1
      for e = 0 to elements-1
         Elem[D[d+r],e,esize] = scalar;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.
F6.1.77   VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

<e> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<size> The data size. It must be one of:
  8 Encoded as imm4<0> = '1'. imm4<3:1> encodes the index[x] of the scalar.
  16 Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.
  32 Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
      for e = 0 to elements-1
          Elem[D[d+r],e,esize] = scalar;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.78   VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the
result in the destination register. The operand and result registers can be quadword or doubleword. They must all be
the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

64-bit SIMD vector variant

Applies when Q == 0.

128-bit SIMD vector variant

Applies when Q == 1.

VEOR{<c>}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be
unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.79 VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows the operation of VEXT doubleword operation for imm = 3.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instruction VEXT (multibyte elements). The pseudo-instruction is never the preferred disassembly.

A1

64-bit SIMD vector variant

Applies when Q == 0.

VEXT{<c>}{<q>}.8 {<Dd>,} <Dn>, <Dm>, #<imm>

128-bit SIMD vector variant

Applies when Q == 1.

VEXT{<c>}{<q>}.8 {<Qd>,} <Qn>, <Qm>, #<imm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;

\(<Dm>\)  Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

\(<\text{imm}>\)  For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the "imm4" field.

For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the "imm4" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  if quadword_operation then
    Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
  else
    D[d] = (D[m]:D[n])<position+63:position>;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.80  VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This instruction is a pseudo-instruction of the VEXT (byte elements) instruction. This means that:

- The encodings in this description are named to match the encodings of VEXT (byte elements).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

F6.1.83 VFMAL (by scalar)

Vector Floating-point Multiply-Add Long to accumulator (by scalar). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

In ARMv8.2 and ARMv8.3, this is an OPTIONAL instruction. From ARMv8.4 it is mandatory for all implementations to support it.

--- Note ---
ID_ISAR6.FHM indicates whether this instruction is supported.

F6.1.87 VFNMA

Vector Fused Negate Multiply Accumulate negates one floating-point register value and multiplies it by another floating-point register value, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

```
F6.1.92 VJCVT

Javascript Convert to signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo $2^{32}$, as held in a 32-bit signed integer.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 then UNPREDICTABLE;

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

#### Assembler symbols

- `<>` For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

- `<>` For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.

- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10

- `<list>` Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }.
  
The register `<Dd>` is encoded in the "D:Vd" field.

- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

- `<align>` When `<size>` == 8, `<align>` must be omitted, otherwise it is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access on page E2-3580*, and the encoding depends on <size>:

- <size> == 8: Encoded in the "index_align<0>" field as 0.
- <size> == 16: Encoded in the "index_align<1:0>" field as 0b00.
- <size> == 32: Encoded in the "index_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 16: <align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
- <size> == 32: <align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode on page F2-3675*.

<Rm> is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F2-3675*.

**Operation for all encodings**

if ConditionPassed() then

    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d],index] = MemU[address,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;

    else
        R[n] = R[n] + ebytes;
VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Offset variant

Applies when Rm == 1111.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]}

Post-indexed variant

Applies when Rm == 1101.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align}>]!}

Post-indexed variant

Applies when Rm != 11x1.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align}>],<Rm>

Decode for all variants of this encoding

if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size);  regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;

### Decode for all variants of this encoding

\begin{verbatim}
regs = 4;
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
\end{verbatim}

**CONSTRAINED UNPREDICTABLE behavior**

If $d+regs > 32$, then one of the following behaviors must occur:

- The instruction is \texttt{UNDEFINED}.
- The instruction executes as \texttt{NOP}.
- One or more of the SIMD and floating-point registers are \texttt{UNKNOWN}. If the instruction specifies writeback, the base register becomes \texttt{UNKNOWN}. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the \texttt{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see Appendix K1 \textit{Architectural Constraints on UNPREDICTABLE behaviors}, and particularly \texttt{VLDI (multiple single elements)} on page K1-7209.

Related encodings: See \textit{Advanced SIMD element or structure load/store} on page F3-3730 for the T32 instruction set, or \textit{Advanced SIMD element or structure load/store} on page F4-3804 for the A32 instruction set.

### Assembler symbols

\texttt{<c>}

For encoding A1, A2, A3 and A4: see \textit{Standard assembler syntax fields} on page F2-3654. This encoding must be unconditional.
For encoding T1, T2, T3 and T4: see Standard assembler syntax fields on page F2-3654.

See Standard assembler syntax fields on page F2-3654.

<size>
Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10
- 64 when size = 11

$list$
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

- { <Dd> }  Single register. Selects the A1 and T1 encodings of the instruction.
- { <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

- 64  64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
- 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            bits(ebytes*8) data;
            if ebytes != 8 then
                data = MemU[address,ebytes];
            else
                = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
                data<31:0> = if BigEndian() then MemU[address+4,4] else MemU[address,4];
                data<63:32> = if BigEndian() then MemU[address,4] else MemU[address+4,4];
                Elem[D[d+r],e] = data;
                address = address + ebytes;
"
if wback then
  if register_index then
    R[n] = R[n] + R[m];
  else
    R[n] = R[n] + 8*regs;
F6.1.96 VLD2 (single 2-element structure to one lane)

Load single 2-element structure to one lane of two registers loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

\text{if n} = 15 \| \text{ d2} > 31 \text{ then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( d2 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD2 (single 2-element structure to one lane)* on page K1-7209.

**Assembler symbols**

- **<c>** For encoding A1, A2 and A3: see *Standard assembler syntax fields* on page F2-3654. This encoding must be unconditional.
  
  For encoding T1, T2 and T3: see *Standard assembler syntax fields* on page F2-3654.

- **<q>** See *Standard assembler syntax fields* on page F2-3654.

- **<size>** Is the data size, encoded in the "size" field. It can have the following values:
  
  - \( 8 \) when \( \text{size} = 00 \)
  
  - \( 16 \) when \( \text{size} = 01 \)
  
  - \( 32 \) when \( \text{size} = 10 \)

- **<list>** Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of:
  
  - \( \{ <Dd>[<index>], <Dd+1>[<index>] \} \) Single-spaced registers, encoded as "spacing" = 0.
  
  - \( \{ <Dd>[<index>], <Dd+2>[<index>] \} \) Double-spaced registers, encoded as "spacing" = 1. Not permitted when \( <size> = 8 \).

  The encoding of "spacing" depends on \( <size> \):
  
  - \( <size> = 16\text{"spacing"} \) is encoded in the "index_align<1>" field.
  
  - \( <size> = 32\text{"spacing"} \) is encoded in the "index_align<2>" field.

  The register \( <Dd> \) is encoded in the "D:Vd" field.

  The permitted values and encoding of \( <index> \) depend on \( <size> \):
  
  - \( <size> = 8\langle index\rangle \) is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.
<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and the encoding depends on <size>:
- <size> == 8Encoded in the "index_align<0>" field as 0.
- <size> == 16Encoded in the "index_align<0>" field as 0.
- <size> == 32Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:
- <size> == 8<align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32<align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

>: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

- The instruction is **UNDEFINED**.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are **UNKNOWN**. If the instruction specifies writeback, the base register becomes **UNKNOWN**. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly `VLD2 (multiple 2-element structures)` on page K1-7209.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-3730 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-3804 for the A32 instruction set.

**Assembler symbols**

- `<c>`
  - For encoding A1 and A2: see *Standard assembler syntax fields* on page F2-3654. This encoding must be unconditional.
  - For encoding T1 and T2: see *Standard assembler syntax fields* on page F2-3654.
- `<q>`
  - See *Standard assembler syntax fields* on page F2-3654.
- `<size>`
  - Is the data size, encoded in the "size" field. It can have the following values:
    - 8 when `size = 00`
    - 16 when `size = 01`
    - 32 when `size = 10`
  - The encoding `size = 11` is reserved.
- `<list>`
  - Is a list containing the 64-bit names of the SIMD&FP registers.
    - The list must be one of:
      
      - \{ `<Dd>`, `<Dd+1>` \}Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1000.
      - \{ `<Dd>`, `<Dd+2>` \}Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1001.
      - \{ `<Dd>`, `<Dd+1>`, `<Dd+2>`, `<Dd+3>` \}Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.
    - The register `<Dd>` is encoded in the "D:Vd" field.
- `<Rn>`
  - Is the general-purpose base register, encoded in the "Rn" field.
- `<align>`
  - Is the optional alignment.
    - Whenever `<align>` is omitted, the standard alignment is used, see *Unaligned data access* on page E2-3580, and is encoded in the "align" field as 0b00.
    - Whenever `<align>` is present, the permitted values are:
      - 64 64-bit alignment, encoded in the "align" field as 0b01.
      - 128 128-bit alignment, encoded in the "align" field as 0b10.
      - 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if `<list>` contains four registers.
  - `:` is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode* on page F2-3675.
<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD3 (single 3-element structure to one lane) on page K1-7210.

Assembler symbols
<ct>
For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional. For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.
<q> See Standard assembler syntax fields on page F2-3654.
<size>
Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10

<list>
Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of:
{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as "spacing" = 0.
{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> = 8.
The encoding of "spacing" depends on <size>:
<size> = 8, "spacing" is encoded in the "index_align<0:6>" field.
<size> = 16, "spacing" is encoded in the "index_align<1:11>" field, and "index_align<0:6>" is set to 0.
<size> = 32, "spacing" is encoded in the "index_align<2:23>" field, and "index_align<1:11>" is set to 0b000.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:

- \(<size> = 8\) <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- \(<size> = 16\) <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- \(<size> = 32\) <index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> is the general-purpose base register, encoded in the "Rn" field.

<Rm> is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode* on page F2-3675.

Alignment

Standard alignment rules apply, see *Alignment support* on page B2-116.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2], index] = MemU[address+ebytes,ebytes];
    Elem[D[d3], index] = MemU[address+2*ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```
F6.1.100  VLD3 (single 3-element structure to all lanes)

Load single 3-element structure and replicate to all lanes of three registers loads one 3-element structure from memory into all lanes of three registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

**CONSTRAINED UNPREDICTABLE behavior**

If \( d3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD3 (multiple 3-element structures) on page K1-7210.

Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.
Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<size> Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10
The encoding size = 11 is reserved.

<list> Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:
  { <Dd>, <Dd+1>, <Dd+2> }Single-spaced registers, encoded in the "type" field as 0b0100.
  { <Dd>, <Dd+2>, <Dd+4> }Double-spaced registers, encoded in the "type" field as 0b0101.
The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
For more information about <Rn>, !, and <Rm>, see The Advanced SIMD addressing mode on page F2-3675.

Operation for all encodings

if ConditionPassed() then

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to one lane) on page K1-7210.

Assembler symbols

<

For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.

>

See Standard assembler syntax fields on page F2-3654.

<size>

Is the data size, encoded in the "size" field. It can have the following values:

8  when size = 00
16  when size = 01
32  when size = 10

:list

Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] }Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> = 16"spacing" is encoded in the "index_align<1>" field.
<size> = 32"spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of `<index>` depend on `<size>`:

- `<size>` == 8, `<index>` is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- `<size>` == 16, `<index>` is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- `<size>` == 32, `<index>` is 0 or 1, encoded in the "index_align<3>" field.

`<Rn>`

Is the general-purpose base register, encoded in the "Rn" field.

`<align>`

Is the optional alignment.

Whenever `<align>` is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and the encoding depends on `<size>`:

- `<size>` == 8, encoded in the "index_align<0>" field as 0.
- `<size>` == 16, encoded in the "index_align<0>" field as 0.
- `<size>` == 32, encoded in the "index_align<1:0>" field as 0b00.

Whenever `<align>` is present, the permitted values and encoding depend on `<size>`:

- `<size>` == 8, `<align>` is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- `<size>` == 16, `<align>` is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
- `<size>` == 32, `<align>` can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

`: ` is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see The Advanced SIMD addressing mode on page F2-3675.

`<Rm>`

Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

### Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[0][d2], index = MemU[address, ebytes];
    Elem[0][d3], index = MemU[address+2*ebytes, ebytes];
    Elem[0][d4], index = MemU[address+3*ebytes, ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
    else
```
**F6.1.103  VLD4 (single 4-element structure to all lanes)**

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode see *The Advanced SIMD addressing mode on page F2-3675.*

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-5308.*

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to all lanes) on page K1-7211.

Assembler symbols
<>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.
<p>See Standard assembler syntax fields on page F2-3654.</p>

<size>
Is the data size, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>when size = 00</td>
</tr>
<tr>
<td>16</td>
<td>when size = 01</td>
</tr>
<tr>
<td>32</td>
<td>when size = 1x</td>
</tr>
</tbody>
</table>

</size>

/list>
Is a list containing the 64-bit names of four SIMD&FP registers.
The list must be one of:

- \{ <Dd>[][], <Dd+1>[][], <Dd+2>[][], <Dd+3>[][] \} Single-spaced registers, encoded in the "T" field as 0.
- \{ <Dd>[][], <Dd+2>[][], <Dd+4>[][], <Dd+6>[][] \} Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
- <size> == 16<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
- <size> == 32<align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```
F6.1.104  VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see Element and structure load/store instructions on page F1-3634. Every element of each register is loaded. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

```
| 1 1 1 0 1 0 0 0 | D | 1 | 0 | Rn | Vd | 0 | 0 | x | size | align | Rm |
```

Offset variant

Applies when Rm == 1111.

\[ \text{VLD4}\{<c>\}{<q>}.<size> <list>, [<Rn>{:<align}>]\]

Post-indexed variant

Applies when Rm == 1101.

\[ \text{VLD4}\{<c>\}{<q>}.<size> <list>, [<Rn>{:<align}>]! \]

    SEE "Related encodings";
if size == '11' then UNDEFINED;
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  d4 = d3 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
```

**CONSTRANGED UNPREDICTABLE behavior**

If $d4 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly $\text{VLD4 (multiple 4-element structures)}$ on page K1-7210.

Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.
Assembler symbols

**<c>**
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

**<q>**
See Standard assembler syntax fields on page F2-3654.

**<size>**
Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

The encoding size = 11 is reserved.

**<list>**
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

- \{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> \} Single-spaced registers, encoded in the "type" field as 0b0000.
- \{ <Dd>, <Dd+2>, <Dd+4>, <Dd+6> \} Double-spaced registers, encoded in the "type" field as 0b0001.

The register <Dd> is encoded in the "D:Vd" field.

**<Rn>**
Is the general-purpose base register, encoded in the "Rn" field.

**<align>**
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

- 64 64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10.
- 256 256-bit alignment, encoded in the "align" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

**<Rm>**
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

Operation for all encodings

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = FALSE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  for e = 0 to elements-1
    Elem[0][d], e = MemU[address,ebytes];
    Elem[0][d+2], e = MemU[address+ebytes+ebytes, ebytes];
    Elem[0][d+4], e = MemU[address+2*bytes, ebytes];
    Elem[0][d+6], e = MemU[address+3*bytes, ebytes];
    address = address + 4*ebytes;
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 32;
```
F6.1.105   **VLDM, VLDMDB, VLDMIA**

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see _Enabling Advanced SIMD and floating-point support_ on page G1-5308.

This instruction is used by the alias VPOP. See _Alias conditions_ on page F6-4812 for details of when each alias is preferred.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-3654.
- `<q>` See Standard assembler syntax fields on page F2-3654.
- `<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
- `!` Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
- `<reglist>` Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
- `<reglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n].imm32;

Assembler symbols
<>
See Standard assembler syntax fields on page F2-3654.

<>
See Standard assembler syntax fields on page F2-3654.

.64
Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

.32
Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd>
Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
The label of the literal data item to be loaded.

For the single-precision scalar or double-precision scalar variants: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

For the half-precision scalar variant: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 2 in the range -510 to 510.

If the offset is zero or positive, \( \text{imm32} \) is equal to the offset and \( \text{add} \) == TRUE.

If the offset is negative, \( \text{imm32} \) is equal to minus the offset and \( \text{add} \) == FALSE.

\[ +/- \]
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
- when \( U = 1 \)

\[ <\text{imm}> \]
For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as \(<\text{imm}>/4\).

For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as \(<\text{imm}>/2\).

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-3613.

**Operation for all encodings**

if ConditionPassed() then  
   EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  
   base = if n == 15 then Align(PC,4) else R[n];  
   address = if add then (base + imm32) else (base - imm32);  
   case esize of  
      when 16  
         S[d] = Zeros(16) : MemA[address,2];  
      when 32  
         S[d] = MemA[address,4];  
      when 64  
         word1 = MemA[address,4];  word2 = MemA[address+4,4];  // Combine the word-aligned words in the correct order for current endianness.  
         D[d] = if BigEndian() then word1:word2 else word2:word1;  

F6.1.108  **VMAX (floating-point)**

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPR2 registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

**CONstrained Unpredictable behavior**

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

<>< For encoding A1: see *Standard assembler syntax fields* on page F2-3654. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields* on page F2-3654.

<>< See *Standard assembler syntax fields* on page F2-3654.

<dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

- F32 when sz = 0
- F16 when sz = 1

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<d> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<n> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<m> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Floating-point maximum and minimum

- max(+0.0, -0.0) = +0.0
- If any input is a NaN, the corresponding result element is the default NaN.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
      if maximum then
        Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
F6.1.109  VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

            Elem[D[d+r],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
— The values of the NZCV flags.
F6.1.110  VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

if Q == '1' && (V<0> == '1' || V<0> == '1' || V<0> == '1') then UNDEFINED;

if sz == '1' && !HaveFP16Ext() then UNDEFINED;

if sz == '1' && InITBlock() then UNPREDICTABLE;
maximum = (op == '0');
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

**CONSTRAINED UNPREDICTABLE behavior**

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

< For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

<> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

<table>
<thead>
<tr>
<th>sz</th>
<th>dt</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>F32</td>
</tr>
<tr>
<td>1</td>
<td>F16</td>
</tr>
</tbody>
</table>

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.

<qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <qn>*2.

<qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<d> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<d> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Floating-point minimum**

- min(+0.0, -0.0) = -0.0
- If any input is a NaN, the corresponding result element is the default NaN.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
F6.1.112   VMIN (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

64-bit SIMD vector variant

Applies when $Q == 0$.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Int(Elem[D:n+r],e,esize], unsigned);
        op2 = Int(Elem[D:m+r],e,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[D:d+r],e,esize] = result<esize-1:0>;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
F6.1.113  VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMIN.

This instruction is not conditional.

A1

64-bit SIMD vector variant

**CONSTRAINED UNPREDICTABLE behavior**

If `InITBlock()` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

\(\mathbf{q}\)

See Standard assembler syntax fields on page F2-3654.

\(\mathbf{dt}\)

Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

\[
\begin{align*}
\text{F32} & \text{ when sz = 0} \\
\text{F16} & \text{ when sz = 1}
\end{align*}
\]

\(\mathbf{Qd}\)

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<\mathbf{Qd}>*2\).

\(\mathbf{Qn}\)

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<\mathbf{Qn}>*2\).

\(\mathbf{Qm}\)

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<\mathbf{Qm}>*2\).

\(\mathbf{Dd}\)

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(\mathbf{Dn}\)

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\(\mathbf{Dm}\)

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

\(\mathbf{Sd}\)

Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

\(\mathbf{Sn}\)

Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.

\(\mathbf{Sm}\)

Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<type>
The data type for the elements of the operands. It must be one of:
- S  Optional in encoding T1/A1. Encoded as U = 0 in encoding T2/A2.
- U  Optional in encoding T1/A1. Encoded as U = 1 in encoding T2/A2.
- I  Available only in encoding T1/A1.

<size>
The data size for the elements of the operands. It must be one of:
- 8  Encoded as size = 0b00.
- 16  Encoded as size = 0b01.
- 32  Encoded as size = 0b10.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[Din[n+r],e,esize,unsigned] * Int(Elem[Din[m+r],e,esize,unsigned],unsigned);
            addend = if add then product else -product;

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F6.1.119 VMLS (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

--- **Note** ---

ARM recommends that software does not use the VMLS instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-5308*.

## Assembler symbols

### \(<c>\)

For encoding A1: see *Standard assembler syntax fields on page F2-3654*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields on page F2-3654*.

### \(<q>\)

See *Standard assembler syntax fields on page F2-3654*.

### \(<\text{type}>\)

The data type for the elements of the operands. It must be one of:

- **S**: Optional in encoding T1/A1. Encoded as \(U = 0\) in encoding T2/A2.
- **U**: Optional in encoding T1/A1. Encoded as \(U = 1\) in encoding T2/A2.
- **I**: Available only in encoding T1/A1.

### \(<\text{size}>\)

The data size for the elements of the operands. It must be one of:

- **8**: Encoded as size = \(0b00\).
- **16**: Encoded as size = \(0b01\).
- **32**: Encoded as size = \(0b10\).

### \(<\text{Qd}>\)

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<\text{Qd}>*2\).

### \(<\text{Qn}>\)

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<\text{Qn}>*2\).

### \(<\text{Qm}>\)

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<\text{Qm}>*2\).

### \(<\text{Dd}>\)

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

### \(<\text{Dn}>\)

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

### \(<\text{Dm}>\)

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[Din[n+r],e,esize],unsigned) * Int(Elem[Din[m+r],e,esize],unsigned);
            addend = if add then product else -product;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

## Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.121   VMLS (by scalar)

Vector Multiply Subtract multiplies elements of a vector by a scalar, and either subtracts the products from corresponding elements of the destination vector.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.123  VMLSL (by scalar)

Vector Multiply Subtract Long multiplies elements of a vector by a scalar, and subtracts the products from corresponding elements of the destination vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

index = UInt(M);

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-3707 for the T32 instruction set, or Advanced SIMD data-processing on page F4-3792 for the A32 instruction set.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields* on page F2-3654.

See *Standard assembler syntax fields* on page F2-3654.

**dt**

Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:

- **S16** when \( U = 0 \), \( size = 01 \)
- **S32** when \( U = 0 \), \( size = 10 \)
- **U16** when \( U = 1 \), \( size = 01 \)
- **U32** when \( U = 1 \), \( size = 10 \)

**qd**

Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as \(<qd>*2\).

**dn**

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**dm[x]**

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If \( dt \) is S16 or U16, \( dm \) is restricted to D0-D7. \( dm \) is encoded in "Vm<2:0>", and \( x \) is encoded in "M:Vm<3>". If \( dt \) is S32 or U32, \( dm \) is restricted to D0-D15. \( dm \) is encoded in "Vm", and \( x \) is encoded in "M".

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Di[n],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Di[n+r],e,esize]; op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else
                            FNeg(FPMul(op1,op2,StandardFPSCRValue()));
                Elem[D[d+r],e,esize] = FPAddElem[Di[d+r],e,esize], fp_addend, StandardFPSCRValue();
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then
                    Elem[D[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
                else
                    Elem[D[d+r],e,esize] = Elem[Di[d+r],e,esize] + addend;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.124  VMOV (between two general-purpose registers and a doubleword floating-point register)

Copy two general-purpose registers to or from a SIMD&FP register copies two words from two general-purpose registers into a doubleword register in the Advanced SIMD and floating-point register file, or from a doubleword register in the Advanced SIMD and floating-point register file to two general-purpose registers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

From general-purpose registers variant

Applies when \( op = 0 \).

\[ \text{VMOV} \{<c>\} \{<q>\} <Dm>, <Rt>, <Rt2> \]

To general-purpose registers variant

Applies when \( op = 1 \).

\[ \text{VMOV} \{<c>\} \{<q>\} <Rt>, <Rt2>, <Dm> \]

Decode for all variants of this encoding

\[ \text{to}_\text{arm_registers} = (op == '1'); t = \text{UInt}(Rt); t2 = \text{UInt}(Rt2); m = \text{UInt}(M:Vm); \]

if \( t == 15 || t2 == 15 \) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

if \text{to}_\text{arm_registers} \&\& \ t == t2 then UNPREDICTABLE;

CONstrained UNPREDICTABLE behavior

If \( \text{to}_\text{arm_registers} \&\& \ t == t2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

From general-purpose registers variant

Applies when \( op = 0 \).

\[ \text{VMOV} \{<c>\} \{<q>\} <Dm>, <Rt>, <Rt2> \]

To general-purpose registers variant

Applies when \( op = 1 \).

Decode for all variants of this encoding

to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(M:Vm);
if t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if to_arm_registers && t == t2 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1
Architectural Constraints on UNPREDICTABLE behaviors, and particularly VMOV (between two general-purpose
registers and a doubleword floating-point register) on page K1-7211.

Assembler symbols

<DM> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "M:Vm" field.
<Rt2> Is the second general-purpose register that <DM>[63:32] will be transferred to or from, encoded in the
"Rt2" field.
<Rt> Is the first general-purpose register that <DM>[31:0] will be transferred to or from, encoded in the "Rt"
field.
<c> See Standard assembler syntax fields on page F2-3654.
<q> See Standard assembler syntax fields on page F2-3654.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = D[m]<31:0>;
        R[t2] = D[m]<63:32>;
    else
        D[m]<31:0> = R[t];
        D[m]<63:32> = R[t2];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
    — The values of the data supplied in any of its registers.
    — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
    — The values of the data supplied in any of its registers.
    — The values of the NZCV flags.
**F6.1.125 VMOV (between general-purpose register and half-precision)**

Copy 16 bits of a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in the bottom 16 bits of a 32-bit SIMD&FP register to the bottom 16 bits of a general-purpose register, or the value held in the bottom 16 bits of a general-purpose register to the bottom 16 bits of a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

**Notes for all encodings**

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.

**Assembler symbols**

<
For encoding A1, A3, A4 and A5: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding A2, T1, T2, T3, T4 and T5: see Standard assembler syntax fields on page F2-3654.

> See Standard assembler syntax fields on page F2-3654.

<dt>
The data type, encoded in the "cmode" field. It can have the following values:
I32 when cmode = 110x
I8 when cmode = 1110
F32 when cmode = 1111

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Sd>
Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<imm>
For encoding A1, A3, A4, A5, T1, T3, T4 and T5: is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-3671.
For encoding A2 and T2: is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "imm4H:imm4L". For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 floating-point instructions on page F2-3672.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = imm32;
    else
        for r = 0 to regs-1
            D[d+r] = imm64;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.127   VMOV (register)

Copy between FP registers copies the contents of one FP register to another.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.128 VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another.

This instruction is an alias of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The description of VORR (register) gives the operational pseudocode for this instruction.

### A1

64-bit SIMD vector variant

Applies when $Q = 0$.

\[ \text{VMOV} \{<c>\}{<q>}{.<dt>} <Dd>, <Dm> \]

is equivalent to

\[ \text{VORR} \{<c>\}{<q>}{.<dt>} <Dd>, <Dm>, <Dm> \]

and is the preferred disassembly when $N:Vn = M:Vm$.

128-bit SIMD vector variant

Applies when $Q = 1$.

\[ \text{VMOV} \{<c>\}{<q>}{.<dt>} <Qd>, <Qm> \]

is equivalent to

\[ \text{VORR} \{<c>\}{<q>}{.<dt>} <Qd>, <Qm>, <Qm> \]

and is the preferred disassembly when $N:Vn = M:Vm$.

### T1

64-bit SIMD vector variant

Applies when $Q = 0$.

\[ \text{VMOV} \{<c>\}{<q>}{.<dt>} <Dd>, <Dm> \]

is equivalent to

\[ \text{VORR} \{<c>\}{<q>}{.<dt>} <Dd>, <Dm>, <Dm> \]

and is the preferred disassembly when $N:Vn = M:Vm$.

128-bit SIMD vector variant

Applies when $Q = 1$.

\[ \text{VMOV} \{<c>\}{<q>}{.<dt>} <Qd>, <Qm> \]
is equivalent to
VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>
and is the preferred disassembly when N:Vn == M:Vm.

**Assembler symbols**

- `<c>`: For encoding A1: see *Standard assembler syntax fields on page F2-3654*. This encoding must be unconditional.
  For encoding T1: see *Standard assembler syntax fields on page F2-3654*.
- `<q>`: See *Standard assembler syntax fields on page F2-3654*.
- `<dt>`: An optional data type. `<dt>` must not be F64, but it is otherwise ignored.
- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.
- `<Qm>`: Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as `<Qm>*2.
- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<Dm>`: Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of **VORR (register)** gives the operational pseudocode for this instruction.
F6.1.129 VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

VMOV{<c>}{<q>}{.<size>} <Dd[x]>, <Rt>

Decode for this encoding

case opc1:opc2 of
  when '1xxx'  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
  when '0xx1'  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
  when '0x00'  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
  when '0x10'  UNDEFINED;

  d = UInt(D:Vd);  t = UInt(Rt);
  if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

T1

VMOV{<c>}{<q>}{.<size>} <Dd[x]>, <Rt>

Decode for this encoding

case opc1:opc2 of
  when '1xxx'  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
  when '0xx1'  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
  when '0x00'  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
  when '0x10'  UNDEFINED;

  d = UInt(D:Vd);  t = UInt(Rt);
  if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-3654.

\(<q>\) See Standard assembler syntax fields on page F2-3654.

\(<\text{size}>\) The data size. It must be one of:

- 8: Encoded as \(\text{opc1}<1> = 1\), \(\text{opc2}\) is encoded in \(\text{opc1}<0>\), \(\text{opc2}\).
- 16: Encoded as \(\text{opc1}<1> = 0\), \(\text{opc2}<0> = 1\), \(\text{opc2}<1>\) is encoded in \(\text{opc1}<0>\), \(\text{opc2}\).
- 32: Encoded as \(\text{opc1}<1> = 0\), \(\text{opc2} = 0\). \(\text{opc1}<0>\) is encoded in \(\text{opc1}<0>\).
- omitted: Equivalent to 32.

\(<\text{Dd}[x]>\) The scalar. The register \(<\text{Dd}>\) is encoded in D:Vd. For details of how \([x]\) is encoded, see the description of \(<\text{size}>\).

\(<\text{Rt}>\) The source general-purpose register.

Operation for all encodings

If \texttt{ConditionPassed()} then

\begin{verbatim}
   EncodingSpecificOperations(); CheckAdvSIMDOrVFPEncabled(TRUE, advsimd);
   \text{Elem}[D[d],index,esize] = R[t]<esize-1:0>;
\end{verbatim}

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.130  VMOV (between general-purpose register and single-precision)

Copy a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in a 32-bit SIMD&FP register to a general-purpose register, or the value held in a general-purpose register to a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

From general-purpose register variant

Applies when \( \text{op} = 0 \).

\[ \text{VMOV}\{<c>\}\{<q>\} <Sn>, <Rt> \]

To general-purpose register variant

Applies when \( \text{op} = 1 \).

\[ \text{VMOV}\{<c>\}\{<q>\} <Rt>, <Sn> \]

Decode for all variants of this encoding

\[ \begin{align*}

\text{if } t &= 15 \text{ then UNPREDICTABLE; } // \text{ARMv8-A removes UNPREDICTABLE for R13}
\end{align*} \]

T1

From general-purpose register variant

Applies when \( \text{op} = 0 \).

\[ \text{VMOV}\{<c>\}\{<q>\} <Sn>, <Rt> \]

To general-purpose register variant

Applies when \( \text{op} = 1 \).

\[ \text{VMOV}\{<c>\}\{<q>\} <Rt>, <Sn> \]

Decode for all variants of this encoding

\[ \begin{align*}
\text{to\_arm\_register} &= (\text{op} == '1') \land \text{t} = \text{UInt}(\text{Rt}); \quad \text{n} = \text{UInt}(\text{Vn}:\text{N}); \\
\text{if } t &= 15 \text{ then UNPREDICTABLE; } // \text{ARMv8-A removes UNPREDICTABLE for R13}
\end{align*} \]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

< Rt > Is the general-purpose register that < Sn > will be transferred to or from, encoded in the "Rt" field.

< Sn > Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Vn:N" field.

< c > See Standard assembler syntax fields on page F2-3654.

< q > See Standard assembler syntax fields on page F2-3654.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.131 VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

\[ \text{cond} \]

\[ 31 \ 28 \ 27 \ 26 \ 25 \ 24 \ | \ 23 \ 22 \ 21 \ 20 \ | \ 19 \ 16 \ 15 \ | \ 12 \ | 11 \ 10 \ 9 \ 8 \ | \ 7 \ 6 \ 5 \ 4 \ | \ 3 \ 2 \ 1 \ 0 \]

A1 variant

\[ \text{VMOV} \{<c>\}{<q>}{<d.t>} <Rt>, <Dn[x]> \]

Decode for this encoding

case U:opc1:opc2 of
  when 'x1xxx' advsimd = TRUE; esize = 8; index = UInt(opc1<0>:opc2);
  when 'x0xx1' advsimd = TRUE; esize = 16; index = UInt(opc1<0>:opc2<1>);
  when '00x00' advsimd = FALSE; esize = 32; index = UInt(opc1<0>);
  when '10x00' UNDEFINED;
  when 'x0x10' UNDEFINED;
  t = UInt(Rt); n = UInt(N:Vn); unsigned = (U == '1');

T1

\[ \text{cond} \]

\[ 15 \ 14 \ 13 \ | 12 \ 11 \ 10 \ 9 \ 8 \ | \ 7 \ 6 \ 5 \ 4 \ | \ 3 \ 2 \ 1 \ 0 \]

T1 variant

\[ \text{VMOV} \{<c>\}{<q>}{<d.t>} <Rt>, <Dn[x]> \]

Decode for this encoding

case U:opc1:opc2 of
  when 'x1xxx' advsimd = TRUE; esize = 8; index = UInt(opc1<0>:opc2);
  when 'x0xx1' advsimd = TRUE; esize = 16; index = UInt(opc1<0>:opc2<1>);
  when '00x00' advsimd = FALSE; esize = 32; index = UInt(opc1<0>);
  when '10x00' UNDEFINED;
  when 'x0x10' UNDEFINED;
  t = UInt(Rt); n = UInt(N:Vn); unsigned = (U == '1');
  if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<e>  See Standard assembler syntax fields on page F2-3654.

<q>  See Standard assembler syntax fields on page F2-3654.

<dt>  The data type. It must be one of:

S8    Encoded as U = 0, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.
S16   Encoded as U = 0, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.
U8    Encoded as U = 1, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.
U16   Encoded as U = 1, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.
32    Encoded as U = 0, opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>.
       omitted  Equivalent to 32.

<Rt>  The destination general-purpose register.

<Do[x]>  The scalar. For details of how [x] is encoded see the description of <dt>.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
   if unsigned then
      R[t] = ZeroExtend(Elem[D[n],index,esize], 32);
   else
      R[t] = SignExtend(Elem[D[n],index,esize], 32);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.132   VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

A1

![Instruction Format](image)

**From general-purpose registers variant**

Applies when op == 0.

VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>

**To general-purpose registers variant**

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>

**Decode for all variants of this encoding**

\[
\text{to\_arm\_registers} = (\text{op} = '1'); \ t = \text{UInt}(\text{Rt}); \ t2 = \text{UInt}(\text{Rt2}); \ m = \text{UInt}(\text{Vm:M}); \\
\text{if } t = 15 || t2 = 15 || m = 31 \text{ then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If to\_arm\_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If m == 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

T1

![Instruction Format](image)
From general-purpose registers variant
Applies when \( \text{op} == 0 \).
\[
\text{VMOV}(<c>){<q>} <Sm>, <Sm1>, <Rt>, <Rt2>
\]

To general-purpose registers variant
Applies when \( \text{op} == 1 \).
\[
\text{VMOV}(<c>){<q>} <Rt>, <Rt2>, <Sm>, <Sm1>
\]

Decode for all variants of this encoding
\[
to\_arm\_registers = (\text{op} == '1'); \ t = \text{UInt}(Rt); \ t2 = \text{UInt}(Rt2); \ m = \text{UInt}(Vm:M);
\]
\[
\text{if } t == 15 \text{ || } t2 == 15 \text{ || } m == 31 \text{ then UNPREDICTABLE;}
\]
\[
\text{if } to\_arm\_registers \&\& t == t2 \text{ then UNPREDICTABLE;}
\]

CONSTRAINED UNPREDICTABLE behavior

If \( to\_arm\_registers \&\& t == t2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If \( m == 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VMOV (between two general-purpose registers and two single-precision registers) on page K1-7211.

Assembler symbols
\(<Rt2>\) Is the second general-purpose register that \(<Sm1>\) will be transferred to or from, encoded in the "Rt2" field.
\(<Rt>\) Is the first general-purpose register that \(<Sm>\) will be transferred to or from, encoded in the "Rt" field.
\(<Sm1>\) Is the 32-bit name of the second SIMD&FP register to be transferred. This is the next SIMD&FP register after \(<Sm>\).
\(<Sm>\) Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Vm:M" field.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.133  VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    S[d] = Zeros(16) : S[m]<31:16>;
```
F6.1.136 VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the FPSCR, a form of the instruction transfers the FPSCR, {N, Z, C, V} condition flags to the APSR, {N, Z, C, V} condition flags.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when HCR.TID0 is set to 1, any VMRS access to FPSID from a Non-secure EL1 mode that would be permitted if HCR.TID0 was set to 0 generates a Hyp Trap exception. For more information, see ID group 0, Primary device identification registers on page G1-5331.

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

A1

```
|31| 28|27 26 25 24|23 22 21 20|19 16|15 12|11 10 9 8 7 6 5 4 3 2 1 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

        else
            Elem[D+d+r],e,esize] = product<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.140   VMUL (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

- P8 when \( \text{op} = 1, \ U = 0, \ 	ext{size} = 00 \)
- P64 when \( \text{op} = 1, \ U = 0, \ 	ext{size} = 10 \)

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<Qd>^*2\).

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<br>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[Din[m+r],e,esize];  op1val = Int(op1, unsigned);
      op2 = Elem[Din[m+r],e,esize];  op2val = Int(op2, unsigned);
      if polynomial then
        product = PolynomialMult(op1,op2);
      else
        product = (op1val*op2val)<2*esize-1:0>
      if long_destination then
        Elem[Q[d>>1],e,2*esize] = product;
      else
        Elem[D[d+r],e,esize] = product<esize-1:0>;
```
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.142 VMULL (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see Advanced SIMD scalars on page F2-3680.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-3707 for the T32 instruction set, or Advanced SIMD data-processing on page F4-3792 for the A32 instruction set.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.
See Standard assembler syntax fields on page F2-3654.

**dt**
Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:
- S16 when \( U = 0 \), size = 01
- S32 when \( U = 0 \), size = 10
- U16 when \( U = 1 \), size = 01
- U32 when \( U = 1 \), size = 10

**qd**
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.

**dn**
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**dm**
Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.

**index**
Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[n], index, esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r], e, esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r], e, esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
                if long_destination then
                    Elem[D[d+r], e, esize] = (op1val*op2val)<esize-1:0>;
                else
                    Elem[D[d+r], e, esize] = (op1val*op2val)<esize-1:0>;
```

```plaintext
```
F6.1.143 VMVN (Immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

### Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.

### Assembler symbols

- **<c>** For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional. For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.
- **<q>** See Standard assembler syntax fields on page F2-3654.
- **<Qd>** Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- **<Dd>** Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- **<imm>** Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-3671.
Operation for all encodings

if \text{ConditionPassed()} \text{ then}
    \text{EncodingSpecificOperations(); CheckAdvSIMDEnabled();}
    \text{for } r = 0 \text{ to } \text{regs-1}
    \quad D[d+r] = \text{NOT}(\text{imm64});

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.144 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

VMVN{<c>}{<q>}{.<dt>} <Qd>, <Qm>

Decode for all variants of this encoding

if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

T1

| 15 14 13 12|11 10 9 8 |7 6 5 4 |3 2 1 0|15 12|11 10 9 8 |7 6 5 4 |3 0 |1 1 1 1 1 1 1 1 |D 1 1 |size 0 0 |Vd 0 0 1 1 |Q M 0 |Vm |

64-bit SIMD vector variant

Applies when Q == 0.

VMVN{<c>}{<q>}{.<dt>} <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMVN{<c>}{<q>}{.<dt>} <Qd>, <Qm>

Decode for all variants of this encoding

if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields* on page F2-3654.

<op>

See *Standard assembler syntax fields* on page F2-3654.

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(D[m+r]);
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.145   VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

            when 64 D[d] = FPNeg(D[m]);
        end
    end
end

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.146 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Note

ARM recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Half-precision scalar variant

Applies when size == 01.

VNMLA{<c>}{<q>}.F16 <Sd>, <Sn>, <Sm>

Single-precision scalar variant

Applies when size == 10.

VNMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Double-precision scalar variant

Applies when size == 11.

VNMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;

F6.1.149  VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (immediate) gives the operational pseudocode for this instruction.

128-bit SIMD vector variant

Applies when Q == 1.
VORN{<c>}{<q>}.I32 {<Qd>,} <Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I32 <Qd>, #~<imm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: For encoding A1 and A2: see *Standard assembler syntax fields on page F2-3654*. This encoding must be unconditional.
  
  For encoding T1 and T2: see *Standard assembler syntax fields on page F2-3654*.

- `<q>`: See *Standard assembler syntax fields on page F2-3654*.

- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.

- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<imm>`: Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of `<imm>`, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-3671*.

**Operation for all encodings**

The description of VORR (immediate) gives the operational pseudocode for this instruction.
F6.1.150   VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields on page F2-3654.*

<q>

See *Standard assembler syntax fields on page F2-3654.*

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if **ConditionPassed()** then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[n+r] OR NOT(D[m+r]);

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.151  VORR (immediate)

Vector Bitwise OR (immediate) performs a bitwise OR between a register value and an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instruction VORN (immediate). The pseudo-instruction is never the preferred disassembly.

Assembler symbols

<i> For encoding A1 and A2: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1 and T2: see Standard assembler syntax fields on page F2-3654.

<ap> See Standard assembler syntax fields on page F2-3654.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-3671.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.152  VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instructions VMOV (register, SIMD), VRSHR (zero), and VSHR (zero). The pseudo-instruction is never the preferred disassembly.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[n+r] OR D[m+r];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.153  VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADAL doubleword operation for data type S16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

\]

\[
\text{D[d] = dest;}
\]
F6.1.155  VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows the operation of VPADD doubleword operation for data type I16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

      Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];
   D[d] = dest;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.156  VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADDL doubleword operation for data type S16.

![Figure showing the operation of VPADDL doubleword operation for data type S16.]

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

    D[d] = dest;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.161  VPOP

Pop SIMD&FP registers from Stack loads multiple consecutive Advanced SIMD and floating-point register file registers from the stack

This instruction is an alias of the VLDMD, VLDMDB, VLDMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VLDMD, VLDMDB, VLDMIA.
- The description of VLDMD, VLDMDB, VLDMIA gives the operational pseudocode for this instruction.

Operation for all encodings

The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.
F6.1.163   VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

        if sat then FPSCR.QC = '1';
F6.1.169 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instructions VQRSHRN (zero), VQRSHRUN (zero), VQSHRN (zero), and VQSHRUN (zero). The pseudo-instruction is never the preferred disassembly.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

For the signed result variant: is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:
S16  when op<0> = 0, size = 00
S32  when op<0> = 0, size = 01
S64  when op<0> = 0, size = 10
U16  when op<0> = 1, size = 00
U32  when op<0> = 1, size = 01
U64  when op<0> = 1, size = 10

The following encodings are reserved:
•  op<0> = 0, size = 11.
•  op<0> = 1, size = 11.

For the unsigned result variant: is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
S16  when size = 00
S32  when size = 01
S64  when size = 10

The encoding size = 11 is reserved.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
    (Elem[D[d],e,esize], sat) = SatQ(operand, esize, dest_unsigned);
    if sat then FPSCR.QC = '1';
F6.1.170 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

<¢> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<¢> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
- S8 when size = 00
- S16 when size = 01
- S32 when size = 10

The encoding size = 11 is reserved.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
  for e = 0 to elements-1
    result = -SInt(Elem[D[m+r],e,esize]);
    (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
    if sat then FPSCR.QC = '1';
F6.1.171 VQRDMLAH

Vector Saturating Rounding Doubling Multiply Accumulate Returning High Half. This instruction multiplies the vector elements of the first source SIMD&FP register with either the corresponding vector elements of the second source SIMD&FP register or the value of a vector element of the second source SIMD&FP register, without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

\texttt{<q>}

See Standard assembler syntax fields on page F2-3654.

\texttt{<dt>}

Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

- \texttt{S16} when size = 01
- \texttt{S32} when size = 10

\texttt{<Qd>}

Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

\texttt{<Qn>}

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

\texttt{<Qm>}

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

\texttt{<Dd>}

Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

\texttt{<Dn>}

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\texttt{<Dm[x]>}

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, \texttt{<Dm>} is restricted to D0-D7. \texttt{<Dm>} is encoded in "Vm<2:0>" and \texttt{x} is encoded in "M:Vm<3>". If <dt> is S32, \texttt{<Dm>} is restricted to D0-D15. \texttt{<Dm>} is encoded in "Vm", and \texttt{x} is encoded in "M".

\texttt{<Dm>}

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Od> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<On> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Om[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Om is restricted to D0-D7. Om is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32, Om is restricted to D0-D15. Om is encoded in "Vm", and x is encoded in "M".

<Om> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    if scalar_form then op2 = SInt(Elem[D|m],index,esize);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = SInt(Elem[D|n+r],e,esize);
            if !scalar_form then op2 = SInt(Elem[D|m+r],e,esize);
            (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
            Elem[D|d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
### F6.1.174 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see VQSHL (register).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r], e, esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r], e, esize] = result;
            if sat then FPSCR.QC = '1';
```
**F6.1.179 VQSHL (register)**

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see VQRSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

```

**Assembler symbols**

- `<c>` For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  - For encoding T1: see Standard assembler syntax fields on page F2-3654.

- `<q>` See Standard assembler syntax fields on page F2-3654.

- `<dt>` Is the data type for the elements of the vectors, encoded in the "U:size" field. It can have the following values:
  - S8 when U = 0, size = 00
  - S16 when U = 0, size = 01
  - S32 when U = 0, size = 10
  - S64 when U = 0, size = 11
  - U8 when U = 1, size = 00
  - U16 when U = 1, size = 01
  - U32 when U = 1, size = 10
  - U64 when U = 1, size = 11

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- `<Qm>` Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

- `<Qn>` Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
   EncodingSpecificOperations();  CheckAdvSIMDEnabled();
   for r = 0 to regs-1
      for e = 0 to elements-1
         shift = SInt(Elem[D[n+r],e,esize]<7:0>);
         operand = Int(Elem[D[m+r],e,esize], unsigned);
         (result,sat) = SatQ(operand << shift, esize, unsigned);
         Elem[D[d+r],e,esize] = result;
         if sat then FPSCR.QC = '1';
```
F6.1.180   VQSHRN (zero)

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the signed truncated results in a doubleword vector.

This instruction is a pseudo-instruction of the VQMOVN, VQMOVUN instruction. This means that:

- The encodings in this description are named to match the encodings of VQMOVN, VQMOVUN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

Assembler symbols

\(<c>\) For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

\(<q>\) See Standard assembler syntax fields on page F2-3654.

\(<dt>\) Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:

- S16 when op<0> = 0, size = 00
- S32 when op<0> = 0, size = 01
- S64 when op<0> = 0, size = 10
- U16 when op<0> = 1, size = 00
U32 when op<0> = 1, size = 01
U64 when op<0> = 1, size = 10

The following encodings are reserved:
• op<0> = 0, size = 11.
• op<0> = 1, size = 11.

<Od> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings
The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.
F6.1.181 VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see VQSRHN, VQSRHUN.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-3533.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

</tbody>
</table>

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>^2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>^2.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.185   VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the
results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal square root estimate and step on page E1-3551.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

64-bit SIMD vector variant

Applies when Q == 0.

VRECPE{<c>}{<q>}.<dt> <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VRECPE{<c>}{<q>}.<dt> <Qd>, <Qm>
Decode for all variants of this encoding

if Q == '1' & (Vd<0> == '1') then UNDEFINED;
if (size == '01' & HaveFP16Ext()) | size IN {'00', '11'} then UNDEFINED;
if size == '01' & InITBlock() then UNPREDICTABLE;
floating_point = (F == '1');
case size of
  when '01' esize = 16; elements = 4;
  when '10' esize = 32; elements = 2;
  d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

CONstrained UNPREDICTABLE behavior

If size == '01' & InITBlock(), then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<dt>
Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
U32    when F = 0, size = 10
F16    when F = 1, size = 01
F32    when F = 1, size = 10

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see Floating-point reciprocal estimate and step on page E1-3550.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        Elem[D[d+r],e,esize] = FPRRecipEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = UnsignedRecipEstimate(Elem[D[m+r],e,esize]);
F6.1.186 VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-3550.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

<as> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

<ap> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- S8 when \( U = 0 \), size = 00
- S16 when \( U = 0 \), size = 01
- S32 when \( U = 0 \), size = 10
- U8 when \( U = 1 \), size = 00
- U16 when \( U = 1 \), size = 01
- U32 when \( U = 1 \), size = 10

<q> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <q>*2.

<qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <qn>*2.

<qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = op1 + op2 + 1;
            Elem[D[d+r],e,esize] = result<esize:1>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
F6.1.191  VRINTA (Advanced SIMD)

Vector Round floating-point to integer towards Nearest with Ties to Away rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

F6.1.202 VRINTZ (Advanced SIMD)

Vector round floating-point to integer towards Zero rounds a vector of floating-point values to integral floating-point values of the same size, using the Round towards Zero rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A1

```
   |111100111|11|10|1011|11|1|0|Vd|0|1|0|1|Q|M|0|Vm|
```

64-bit SIMD vector variant

Applies when Q == 0.

VRINTZ<q>.<dt> <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VRINTZ<q>.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
rounding = FPRounding_ZERO; exact = FALSE;
case size of
  when '01' esize = 16; elements = 4;
  when '10' esize = 32; elements = 2;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

T1

```
   |111100111|11|10|1011|11|1|0|Vd|0|1|0|1|Q|M|0|Vm|
```

64-bit SIMD vector variant

Applies when Q == 0.

VRINTZ<q>.<dt> <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VRINTZ<q>.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

if InITBlock() then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<q>` See *Standard assembler syntax fields* on page F2-3654.
- `<dt>` Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
  - F16 when size = 01
  - F32 when size = 10
- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- `<Qm>` Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<Dm>` Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
  for e = 0 to elements-1
    op1 = Elem[D[m+r],e,esize];
    result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
    Elem[D[d+r],e,esize] = result;
F6.1.203   VRINTZ (floating-point)

Round floating-point to integer towards Zero rounds a floating-point value to an integral floating-point value of the same size, using the Round towards Zero rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);

**CONSTRAINED UNPREDICTABLE behavior**

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

- See Standard assembler syntax fields on page F2-3654.

- See Standard assembler syntax fields on page F2-3654.

- Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

- Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

- Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of 
  when 16
    S[d] = Zeros(16) : FPRoundInt(S[m]<15:_>, FPSCR, rounding, exact);
  when 32
    S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
  when 64
    D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
F6.1.204 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

<>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.
<dt>
Is the data type for the elements of the vectors, encoded in the "U:size" field. It can have the following values:
S8   when U = 0, size = 00
S16  when U = 0, size = 01
S32  when U = 0, size = 10
S64  when U = 0, size = 11
U8   when U = 1, size = 00
U16  when U = 1, size = 01
U32  when U = 1, size = 10
U64  when U = 1, size = 11

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Dr>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Mr>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Nr>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
      for e = 0 to elements-1
          shift = SInt(Elem[D[n+r],e,esize]<7:0>);
          round_const = 1 << (-shift-1); // 0 for left shift, 2^(n-1) for right shift
          result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) << shift;
          Elem[D[d+r],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.205  VRSHR

Vector Rounding Shift Right takes each element in a vector, right shifts them by an immediate value, and places the
rounded results in the destination vector. For truncated results, see VSHR.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**Notes for all encodings**

Related encodings: See *Advanced SIMD one register and modified immediate* on page F3-3716 for the T32 instruction set, or *Advanced SIMD one register and modified immediate* on page F4-3801 for the A32 instruction set.

**Assembler symbols**

<
For encoding A1: see *Standard assembler syntax fields* on page F2-3654. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields* on page F2-3654.

<q>
See *Standard assembler syntax fields* on page F2-3654.

<type>
Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:
  S when U = 0
  U when U = 1

<size>
Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
  8 when L = 0, imm6<5:3> = 001
  16 when L = 0, imm6<5:3> = 01x
  32 when L = 0, imm6<5:3> = 1xx
  64 when L = 1, imm6<5:3> = xxx

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Om>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm>
Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  round_const = 1 << (shift_amount - 1);
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = (Int(Elem[D+m+r],e,esize], unsigned) + round_const) >> shift_amount;
      Elem[D+d+r],e,esize] = result- esize-1:0;
```
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.206 VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another.

This instruction is a pseudo-instruction of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

### 64-bit SIMD vector variant

Applies when Q == 0.

VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

### 128-bit SIMD vector variant

Applies when Q == 1.

VRSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

### T1

#### 64-bit SIMD vector variant

Applies when Q == 0.

VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

#### 128-bit SIMD vector variant

Applies when Q == 1.
VRSHR{<c>}{<q>}{.dt} <Qd>, <Qm>, #0
is equivalent to
VORR{<c>}{<q>}{.dt} <Qd>, <Qm>, <Qm>
and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
   For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

Operation for all encodings

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.207  VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see VSHRN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

  when '001xxx'  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
  when '01xxxx'  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
  when '1xxxxx'  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.
Assembler symbols

- <c> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  For encoding T1: see Standard assembler syntax fields on page F2-3654.

- <q> See Standard assembler syntax fields on page F2-3654.

- <size> Is the data size for the elements of the vectors, encoded in the "imm6<5:3>" field. It can have the following values:
  - 16 when imm6<5:3> = 001
  - 32 when imm6<5:3> = 01x
  - 64 when imm6<5:3> = 1xx

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

- <imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  round_const = 1 << (shift_amount-1);
  for e = 0 to elements-1
    result = LSR(Elem[Qin[m>>1],e,2*esize] + round_const, shift_amount);
    Elem[D[d],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector.

This instruction is a pseudo-instruction of the VMOVN instruction. This means that:

- The encodings in this description are named to match the encodings of VMOVN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VMOVN gives the operational pseudocode for this instruction.

### A1 variant

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

### T1 variant

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

### Assembler symbols

- `<c>`: For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  
  For encoding T1: see Standard assembler syntax fields on page F2-3654.

- `<q>`: See Standard assembler syntax fields on page F2-3654.

- `<dt>`: Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
  
  I16 when size = 00
  I32 when size = 01
  I64 when size = 10

  The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of VMOVN gives the operational pseudocode for this instruction.
F6.1.209  VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-3550.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

  when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

CONstrained UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
  U32 when F = 0, size = 10
  F16 when F = 1, size = 01
  F32 when F = 1, size = 10

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see Floating-point reciprocal estimate and step on page E1-3550.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        Elem[D+d+r],e,esize = FPRsqrtEstimate(Elem[D+m+r],e,esize), StandardFPSCRValue());
      else
        Elem[D+d+r],e,esize = UnsignedRSqrtEstimate(Elem[D+m+r],e,esize));
F6.1.210 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-3550.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

      Elem[D+d+r],e,esize] = Elem[D+d+r],e,esize] + result;
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.212   VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see VSUBHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.213 VSDOT (by element)

Dot Product index form with signed integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In ARMv8.2 and ARMv8.3, this is an OPTIONAL instruction. From ARMv8.4 it is mandatory for all implementations to support it.

--- Note ---
ID_ISAR6.DP indicates whether this instruction is supported.

A1

ARMv8.2

  D[d+r] = result;
F6.1.214  VSDOT (vector)

Dot Product vector form with signed integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of the corresponding 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In ARMv8.2 and ARMv8.3, this is an optional instruction. From ARMv8.4 it is mandatory for all implementations to support it.

Note

ID_ISAR6.DP indicates whether this instruction is supported.

    S[d] = if ConditionHolds(cond) then S[n] else S[m];
  when 64
    D[d] = if ConditionHolds(cond) then D[n] else D[m];
```

### Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.216   **VSHL** (Immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.

Assembler symbols

\(<c>\) For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.
\(<q>\) See Standard assembler syntax fields on page F2-3654.
\(<\text{size}>\) Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
  8  when \( L = 0 \), \( \text{imm6}<5:3> = 001 \)
  16 when \( L = 0 \), \( \text{imm6}<5:3> = 01x \)
  32 when \( L = 0 \), \( \text{imm6}<5:3> = 1xx \)
  64 when \( L = 1 \), \( \text{imm6}<5:3> = xxx \)
\(<q_d>\) Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<q_d>\)*2.
\(<q_m>\) Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as \(<q_m>\)*2.
\(<d_d>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
\(<d_m>\) Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
\(<\text{imm}>\) Is an immediate value, in the range 0 to \(<\text{size}>\)-1, encoded in the "imm6" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
F6.1.217  VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see VRSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Assembler symbols

<<> For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<dt> Is the data type for the elements of the vectors, encoded in the "U:size" field. It can have the following values:

- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- S64 when U = 0, size = 11
- U8 when U = 1, size = 00
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10
- U64 when U = 1, size = 11

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
F6.1.218 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

• 8-bit, 16-bit, or 32-bit signed integers.
• 8-bit, 16-bit, or 32-bit unsigned integers.
• 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

<tr>
<td>16</td>
<td>Encoded as imm6&lt;5:4&gt; = 0b01</td>
<td>Encoded as size = 0b01</td>
</tr>
<tr>
<td>32</td>
<td>Encoded as imm6&lt;5&gt; = 1</td>
<td>Encoded as size = 0b10</td>
</tr>
</tbody>
</table>

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> The immediate value. <imm> must lie in the range 1 to <size>, and:

- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
  - If <size> == 8, <imm> is encoded in imm6<2:0>.
  - If <size> == 16, <imm> is encoded in imm6<3:0>.
  - If <size> == 32, <imm> is encoded in imm6<4:0>.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.219 \hspace{0.2cm} \textbf{VSHR}

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see VRSHR.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. \]

is equivalent to

\[
\text{VMOVN}\{<c>\}{<q>}.<dt> \text{ <Dd>, <Qm>}
\]

and is never the preferred disassembly.

Assembler symbols

- For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  - For encoding T1: see Standard assembler syntax fields on page F2-3654.
- For encoding <c> see Standard assembler syntax fields on page F2-3654.
- <q>
- <dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
  - I16 when size = 00
  - I32 when size = 01
  - I64 when size = 10
  - The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of VMOVN gives the operational pseudocode for this instruction.
F6.1.223 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**Notes for all encodings**

Related encodings: See Advanced SIMD one register and modified immediate on page F3-3716 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-3801 for the A32 instruction set.

**Assembler symbols**

- `<c>`: For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  For encoding T1: see Standard assembler syntax fields on page F2-3654.
- `<q>`: See Standard assembler syntax fields on page F2-3654.
- `<size>`: Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
  - 8 when L = 0, imm6<5:3> = 001
  - 16 when L = 0, imm6<5:3> = 01x
  - 32 when L = 0, imm6<5:3> = 1xx
  - 64 when L = 1, imm6<5:3> = xxx
- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.
- `<Qm>`: Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>*2.
- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<Dm>`: Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- `<imm>`: Is an immediate value, in the range 0 to `<size>-1`, encoded in the "imm6" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  mask = LSL(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
      Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.224 VSQRT

Square Root calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q> See Standard assembler syntax fields on page F2-3654.

<size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
  8 when L = 0, imm6<5:3> = 001
  16 when L = 0, imm6<5:3> = 01x
  32 when L = 0, imm6<5:3> = 1xx
  64 when L = 1, imm6<5:3> = xxx

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  mask = LSR(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSR(Elem[D[m+r],e,esize], shift_amount);
      Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.227 VST1 (single element from one lane)

Store single element from one lane of one register stores one element to memory from one element of a register. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

if n == 15 then UNPREDICTABLE;

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<c>
For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<size>
Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10

<list>
Is a list containing the single 64-bit name of the SIMD&FP register holding the element.
The list must be { <Dd>[<index>] }.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
<size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.
Whenever \(<align>\) is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and the encoding depends on \(<size>\):
\(<size> == 8\) Encoded in the "index_align<0>" field as 0.
\(<size> == 16\) Encoded in the "index_align<1:0>" field as 0b00.
\(<size> == 32\) Encoded in the "index_align<2:0>" field as 0b000.
Whenever \(<align>\) is present, the permitted values and encoding depend on \(<size>\):
\(<size> == 16\) is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
\(<size> == 32\) is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.
: is the preferred separator before the \(<align>\) value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.
\(<Rm>\) Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  MemU[address,ebytes] = Elem[D[d],index];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + ebytes;
VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Constrained UNPREDICTABLE behavior
If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.
CONSTRUED UNPREDICTABLE behavior

If $d \text{+} \text{regs} > 32$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Post-indexed variant

Applies when $Rm == 1101$.

$\text{VST1}\{<c>\}{<q>}.<\text{size}> <\text{list}>, [<Rn>\{:<\text{align}>\}]!$

Notes for all encodings

For more information about the CONSTRUED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST1 (multiple single elements) on page K1-7211.
Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.

Assembler symbols

**<>** For encoding A1, A2, A3 and A4: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1, T2, T3 and T4: see Standard assembler syntax fields on page F2-3654.

**<>** See Standard assembler syntax fields on page F2-3654.

**<size>** Is the data size, encoded in the "size" field. It can have the following values:

8 when size = 00
16 when size = 01
32 when size = 10
64 when size = 11

**<list>** Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

{ <Dd> } Single register. Selects the A1 and T1 encodings of the instruction.
{ <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.
The register <Dd> is encoded in the "D:Vd" field.

**<Rn>** Is the general-purpose base register, encoded in the "Rn" field.

**<align>** Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

64 64-bit alignment, encoded in the "align" field as 0b01.
128 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

**<Rm>** Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
For more information about <Rn>, !, and <Rm>, see The Advanced SIMD addressing mode on page F2-3675.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  for r = 0 to regs-1
    for e = 0 to elements-1
      if ebytes != 8 then
        MemU[address,ebytes] = Elem[0][d+r],e;
else
  - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
  bits(64) data = Elem[D[d+r],e];
  MemU[address,4] = if BigEndian() then data<63:32> else data<31:0>;
  MemU[address+4,4] = if BigEndian() then data<31:0> else data<63:32>;
  address = address + ebytes;
if wback then
  if register_index then
    R[n] = R[n] + R[m];
  else
    R[n] = R[n] + 8*regs;
F6.1.229   **VST2 (single 2-element structure from one lane)**

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST2 (single 2-element structure from one lane) on page K1-7212.

**Assembler symbols**

- `<c>`
  - For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
  - For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.

- `<q>`
  - See Standard assembler syntax fields on page F2-3654.

- `<size>`
  - Is the data size, encoded in the "size" field. It can have the following values:
    - 8 when size = 00
    - 16 when size = 01
    - 32 when size = 10

- `<list>`
  - Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.
    - The list must be one of:
      - \{ <Dd>[<index>], <Dd+1>[<index>] \} Single-spaced registers, encoded as "spacing" = 0.
      - \{ <Dd>[<index>], <Dd+2>[<index>] \} Double-spaced registers, encoded as "spacing" = 1. Not permitted when `<size>` == 8.

---

**F6-5138**

*Copyright © 2013-2018 ARM Limited or its affiliates. All rights reserved.*

ARM DDI 0487D.a

Non-Confidential

ID103018
The encoding of "spacing" depends on <size>:
- <size> == 16: "spacing" is encoded in the "index_align<1>" field.
- <size> == 32: "spacing" is encoded in the "index_align<2>" field.
The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:
- <size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<align> is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and the encoding depends on <size>:
- <size> == 8: Encoded in the "index_align<0>" field as 0.
- <size> == 16: Encoded in the "index_align<0>" field as 0.
- <size> == 32: Encoded in the "index_align<1:0>" field as 0b00.
Whenever <align> is present, the permitted values and encoding depend on <size>:
- <size> == 8<align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32<align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm> is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```
VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see Element and structure load/store instructions on page F1-3634. Every element of each register is saved. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

\text{regs} &= 1; \quad \text{if align == '11' then UNDEFINED;}
\text{if size == '11' then UNDEFINED;}
\text{inc} &= \text{if type == '1001' then 2 else 1;}
\text{alignment} &= \text{if align == '00' then 1 else 4 << UInt(align);}
\text{ebytes} &= 1 << \text{UInt(size);}
\text{elements} &= 8 \text{ DIV ebytes;}
\text{d} &= \text{UInt(D:Vd)}; \quad \text{d2} = \text{d + inc}; \quad \text{n} = \text{UInt(Rn)}; \quad \text{m} = \text{UInt(Rm)};
\text{wback} &= (m != 15); \quad \text{register_index} = (m != 15 && m != 13);
\text{if n == 15 || d2+regs > 32 then UNPREDICTABLE;}
\end{align*}
\]

CONSTRAINED UNPREDICTABLE behavior

If \( d2+regs > 32 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T2

\text{if n == 15 || d2+regs > 32 then UNPREDICTABLE;}
\end{align*}
\]
CONSTRANGED UNPREDICTABLE behavior

If d2+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST2 (multiple 2-element structures) on page K1-7211.

Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.

Assembler symbols

<\> For encoding A1 and A2: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1 and T2: see Standard assembler syntax fields on page F2-3654.

<\>| See Standard assembler syntax fields on page F2-3654.

<size> Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10
The encoding size = 11 is reserved.

<\list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- \{ <Dd>, <Dd+1> \} Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1000.
- \{ <Dd>, <Dd+2> \} Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1001.
- \{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> \} Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<\Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

- 64 64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10.
- 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <\list> contains four registers.
: is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode* on page F2-3675.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode* on page F2-3675.

**Operation for all encodings**

```c
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  for r = 0 to regs-1
    for e = 0 to elements-1
      MemU[address, ebytes] = Elem[D[d+r], e];
      MemU[address+ebytes, ebytes] = Elem[D[d2+r], e];
      address = address + 2*ebytes;
    if wback then
      if register_index then
        R[n] = R[n] + R[m];
      else
        R[n] = R[n] + 16*regs;
  for r = 0 to regs-1
    for e = 0 to elements-1
      MemU[address, ebytes] = Elem[D[d+r], e];
```

```c
if wback then
  if register_index then
    R[n] = R[n] + R[m];
  else
    R[n] = R[n] + 16*regs;
```
F6.1.231 VST3 (single 3-element structure from one lane)

Store single 3-element structure from one lane of three registers stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

Notes for all encodings

For more information about the CONSTRUED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly \textit{VST3 (single 3-element structure from one lane)} on page K1-7212.

Assembler symbols

\(<c>\) For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-3654.

\(<q>\) See Standard assembler syntax fields on page F2-3654.

\(<\text{size}>\) Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size == 00
- 16 when size == 01
- 32 when size == 10

\(<\text{list}>\) Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.

The list must be one of:
- \{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] \} Single-spaced registers, encoded as "spacing" = 0.
- \{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] \} Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
The encoding of "spacing" depends on <size>:

- <size> == 8 "spacing" is encoded in the "index_align<0>" field.
- <size> == 16 "spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.
- <size> == 32 "spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

- <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.

<rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

Alignment

Standard alignment rules apply, see Alignment support on page B2-116.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];
  MemU[address, ebytes] = Elem[D[d], index];
  MemU[address+ebytes, ebytes] = Elem[D[d2], index];
  MemU[address+2*ebytes, ebytes] = Elem[D[d3], index];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 3*ebytes;
  else
    R[n] = R[n] + 3*ebytes;
F6.1.232 VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see Element and structure load/store instructions on page F1-3634. Every element of each register is saved. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**Offset variant**

Applies when Rm == 1111.

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

**Post-indexed variant**

Applies when Rm == 1101.

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

**Post-indexed variant**

Applies when Rm != 11x1.

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

**Decode for all variants of this encoding**

if size == '11' || align<1> == '1' then UNDEFINED;

```plaintext
case type of
  when '0100'
    inc = 1;
  when '0101'
    inc = 2;
  otherwise
    decoder"; 
alignment = if align<0> == '0' then 1 else 10;
```

```plaintext
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1, Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST3 (multiple 3-element structures) on page K1-7212.

Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

<q>
See Standard assembler syntax fields on page F2-3654.

<size>
Is the data size, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>00</td>
</tr>
<tr>
<td>16</td>
<td>01</td>
</tr>
<tr>
<td>32</td>
<td>10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

<list>
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

- \{ <Dd>, <Dd+1>, <Dd+2> \} Single-spaced registers, encoded in the "type" field as 0b0100.
- \{ <Dd>, <Dd+2>, <Dd+4> \} Double-spaced registers, encoded in the "type" field as 0b0101.
The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01.
:
is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2], e];
        MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;
        
```

F6.1.233  VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-3675.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST4 (single 4-element structure from one lane) on page K1-7212.

**Assembler symbols**

- For encoding A1, A2 and A3: see *Standard assembler syntax fields on page F2-3654*. This encoding must be unconditional.
- For encoding T1, T2 and T3: see *Standard assembler syntax fields on page F2-3654*.

- See *Standard assembler syntax fields on page F2-3654*.
- Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10
- Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.
The list must be one of:
  - { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] } Single-spaced registers, encoded as "spacing" = 0.
{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:
<size> == 16"spacing" is encoded in the "index_align<1:0>" field.
<size> == 32"spacing" is encoded in the "index_align<2:0>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:
<size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and the encoding depends on <size>:
<size> == 8Encoded in the "index_align<0>" field as 0.
<size> == 16Encoded in the "index_align<0>" field as 0.
<size> == 32Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 8<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 16<align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 32<align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-3675.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; isize = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, isize);

**Notes for all encodings**
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST4 (multiple 4-element structures) on page K1-7212.

Related encodings: See Advanced SIMD element or structure load/store on page F3-3730 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-3804 for the A32 instruction set.
Assembler symbols

\(<c>\)  For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.  
For encoding T1: see Standard assembler syntax fields on page F2-3654.

\(<q>\)  See Standard assembler syntax fields on page F2-3654.

\(\langle\text{size}\rangle\)  Is the data size, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>when size = 00</td>
</tr>
<tr>
<td>16</td>
<td>when size = 01</td>
</tr>
<tr>
<td>32</td>
<td>when size = 10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

\(\langle\text{list}\rangle\)  Is a list containing the 64-bit names of the SIMD&FP registers.  
The list must be one of:

- \{ \langle Dd \rangle, \langle Dd+1 \rangle, \langle Dd+2 \rangle, \langle Dd+3 \rangle \} Single-spaced registers, encoded in the "type" field as 0b0000.
- \{ \langle Dd \rangle, \langle Dd+2 \rangle, \langle Dd+4 \rangle, \langle Dd+6 \rangle \} Double-spaced registers, encoded in the "type" field as 0b0001.

The register \(Dd\) is encoded in the "D:Vd" field.

\(\langle Rn \rangle\)  Is the general-purpose base register, encoded in the "Rn" field.

\(\langle align \rangle\)  Is the optional alignment.  
Whenever \(align\) is omitted, the standard alignment is used, see Unaligned data access on page E2-3580, and is encoded in the "align" field as 0b00.  
Whenever \(align\) is present, the permitted values are:

- 64  64-bit alignment, encoded in the "align" field as 0b01.
- 128  128-bit alignment, encoded in the "align" field as 0b10.
- 256  256-bit alignment, encoded in the "align" field as 0b11.

\(\langle Rm \rangle\)  Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-3675.

Operation for all encodings

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  for e = 0 to elements-1
    MemU[address, ebytes] = Elem[D[d], e];
    MemU[address+ebytes, ebytes] = Elem[D[d2], e];
    MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
    MemU[address+3*ebytes, ebytes] = Elem[D[d4], e];
    address = address + 4*ebytes;
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 32;
```
F6.1.235   VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the alias VPUSH. See Alias conditions on page F6-5166 for details of when each alias is preferred.

A1

\[
\begin{array}{ccccccccc}
\text{cond} & \text{imm8\<7:1\>} & \text{Rn} & \text{Vd} & \text{imm8\<0\>}
\end{array}

\]

CONSTRANGED UNPREDICTABLE behavior

If \( \text{regs} == 0 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If \( \text{regs} > 16 \) \&\& \( (d+\text{regs}) > 32 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Assembler symbols

• <c> See Standard assembler syntax fields on page F2-3654.
• <q> See Standard assembler syntax fields on page F2-3654.
• <size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
• <rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecates use of the PC.
• ! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
• <sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
• <dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.
Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
  address = if add then R[n] else R[n]-imm32;
  for r = 0 to regs-1
    if single_regs then
      MemA[address,4] = S[d+r]; address = address+4;
    else
      // Store as two word-aligned words in the correct order for current endianness.
      MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
      MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
      address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
F6.1.236   VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Notes for all encodings
For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols
• <c> See Standard assembler syntax fields on page F2-3654.
• <q> See Standard assembler syntax fields on page F2-3654.
• .64 Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
• <Dd> Is the 64-bit name of the SIMD&FP source register, encoded in the "D:Vd" field.
• .32 Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
• <Sd> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vd:D" field.
• <Rn> Is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
+/−  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
   -  when U = 0
   +  when U = 1

<imm> For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

Operation for all encodings

**Assembler symbols**

<>

For encoding A1: see *Standard assembler syntax fields* on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

〈dt〉
Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:

- I8 when size = 00
- I16 when size = 01
- I32 when size = 10
- I64 when size = 11

〈Qd〉
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

〈Qn〉
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

〈Qm〉
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

〈Dd〉
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

〈Dn〉
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

〈Dm〉
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] - Elem[D[m+r],e,esize];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.239  VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see VRSUBHN.

There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

**128-bit SIMD vector variant**

Applies when Q == 1.

VSWP{<c>}{<q>}{.<dt>} <Qd>, <Qm>

**Decode for all variants of this encoding**

if size != '00' then UNDEFINED;
if Q == '1' & (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

**Assembler symbols**

For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-3654.

dq
See Standard assembler syntax fields on page F2-3654.

dt
An optional data type. It is ignored by assemblers, and does not affect the encoding.

qd
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(q_d\)*2.

qm
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as \(q_m\)*2.

qd
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

qm
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for \(r = 0\) to \(regs-1\)
        if \(d == m\)
            \(D[d+r] = \text{bits}(64)\) UNKNOWN;
        else
            \(D[d+r] = Din[m+r];\)
            \(D[m+r] = Din[d+r];\)

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.243 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

A1

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 |12|11 10 9 8 |7 6 5 4 |3 |0 |

| 1 1 1 1 | 0 | 1 | 1 | D | 1 | 1 | Vn | Vd | 1 | 0 | len | N | op | M | 0 | Vm |
```

VTBL variant

Applies when \( op == 0 \).

\[
\text{VTBL}\{<c>\}{<q>}.8 <Dd>, <list>, <Dm>
\]

VTBX variant

Applies when \( op == 1 \).

\[
\text{VTBX}\{<c>\}{<q>}.8 <Dd>, <list>, <Dm>
\]

Decode for all variants of this encoding

\[
is\_vtbl = (op == '0');
\|
\text{length} = \text{UInt}(len)+1;
\|
d = \text{UInt}(D:Vd);
\|
n = \text{UInt}(N:Vn);
\|
m = \text{UInt}(M:Vm);
\|
\text{if } n+\text{length} > 32 \text{ then UNPREDICTABLE;}
\]

CONSTRANDED UNPREDICTABLE behavior

If \( n + \text{length} > 32 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

T1

```
| 15 14 13 12|11 10 9 8 |7 6 5 4 |3 |0 |15 |12|11 10 9 8 |7 6 5 4 |3 |0 |

| 1 1 1 1 | 1 | 1 | 1 | D | 1 | 1 | Vn | Vd | 1 | 0 | len | N | op | M | 0 | Vm |
```

VTBL variant

Applies when \( op == 0 \).

\[
\text{VTBL}\{<c>\}{<q>}.8 <Dd>, <list>, <Dm>
\]
VTBX variant

Applies when op == 1.

VTBX{{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Decode for all variants of this encoding

is_vtbl = (op == '0');  length = UInt(len)+1;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;

CONSTRANGED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-3654.

<op>
See Standard assembler syntax fields on page F2-3654.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<list>
The vectors containing the table. It must be one of:

{<Dn>} Encoded as len = 0b00.
{<Dn>, <Dn+1>} Encoded as len = 0b01.
{<Dn>, <Dn+1>, <Dn+2>} Encoded as len = 0b10.
{<Dn>, <Dn+1>, <Dn+2>, <Dn+3}> Encoded as len = 0b11.

<Dm>
Is the 64-bit name of the SIMD&FP source register holding the indices, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];
    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
else
  if is_vtbl then
    Elem[D[d],i,8] = Zeros(8);
  // else Elem[D[d],i,8] unchanged

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.244 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VTRN doubleword operations.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-5308.

This instruction is used by the pseudo-instructions VUZP (alias) and VZIP (alias). The pseudo-instruction is never the preferred disassembly.

Operational information
If CPSR.DIT is 1 and this instruction passes its condition execution check:
• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
— The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.245 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

      else
        element1 = UInt(Elem[operand1, 4 * e + i, esize DIV 4]);
        element2 = UInt(Elem[operand2, 4 * e + i, esize DIV 4]);
      res = res + element1 * element2;
      Elem[result, e, esize] = Elem[result, e, esize] + res;
    D[d+r] = result;
```
F6.1.248  VUZP

Vector Unzip de-interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VUZP doubleword operation for data type 8.

<table>
<thead>
<tr>
<th>VUZP.8, doubleword</th>
<th>Register state before operation</th>
<th>Register state after operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dd</td>
<td>A7 A6 A5 A4 A3 A2 A1 A0</td>
<td>B6 B4 B2 B0</td>
</tr>
<tr>

Assembler symbols

- For encoding A1: see Standard assembler syntax fields on page F2-3654. This encoding must be unconditional.
- For encoding T1: see Standard assembler syntax fields on page F2-3654.

- For the 64-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
The encoding size = 1x is reserved.

- For the 128-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10
The encoding size = 11 is reserved.

- Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

- Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
EncodingspecificOperations(); CheckAdvSIMDEnabled();
if quadword_operation then
  if d == m then
    Q[d>>1] = bits(128) UNKNOWN;  Q[m>>1] = bits(128) UNKNOWN;
  else
    zipped_q = Q[m>>1]:Q[d>>1];
    for e = 0 to (128 DIV esize) - 1
      Elem[Q[d>>1],e,esize] = Elem[zipped_q,2*e,esize];
      Elem[Q[m>>1],e,esize] = Elem[zipped_q,2*e+1,esize];
  else
    if d == m then
      D[d] = bits(64) UNKNOWN;  D[m] = bits(64) UNKNOWN;
    else
      zipped_d = D[m]:D[d];
      for e = 0 to (64 DIV esize) - 1
        Elem[D[d],e,esize] = Elem[zipped_d,2*e,esize];
        Elem[D[m],e,esize] = Elem[zipped_d,2*e+1,esize];
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Part G

The AArch32 System Level Architecture
Chapter G1
The AArch32 System Level Programmers’ Model

This chapter gives a system level description of the programmers’ model for execution in AArch32 state. It contains the following sections:

- About the AArch32 System level programmers’ model on page G1-5208.
- Exception levels on page G1-5209.
- Exception terminology on page G1-5210.
- Execution state on page G1-5212.
- Instruction Set state on page G1-5214.
- Security state on page G1-5215.
- Security state, Exception levels, and AArch32 execution privilege on page G1-5218.
- Virtualization on page G1-5220.
- AArch32 state PE modes, and general-purpose and Special-purpose registers on page G1-5222.
- Process state, PSTATE on page G1-5231.
- Instruction set states on page G1-5237.
- Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239.
- Routing of aborts taken to AArch32 state on page G1-5258.
- Exception return to an Exception level using AArch32 on page G1-5261.
- Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-5266.
- AArch32 state exception descriptions on page G1-5274.
- Reset into AArch32 state on page G1-5296.
- Mechanisms for entering a low-power state on page G1-5300.
- The AArch32 System register interface on page G1-5305.
- Advanced SIMD and floating-point support on page G1-5308.
- Configurable instruction enables and disables, and trap controls on page G1-5314.
G1.1 About the AArch32 System level programmers’ model

An application programmer has only a restricted view of the system. The System level programmers’ model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers’ model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers’ model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- Exception levels on page G1-5209.
- Exception terminology on page G1-5210.
- Execution state on page G1-5212.
- Instruction Set state on page G1-5214.
- Security state on page G1-5215.
- Virtualization on page G1-5220.

The rest of this chapter describes the system level programmers’ model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - Chapter G4 The AArch32 System Level Memory Model describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.
    
    ___ Note ___
    
    Chapter E2 The AArch32 Application Level Memory Model describes the application level view of the memory model.

  - Chapter G5 The AArch32 Virtual Memory System Architecture describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.

- The AArch32 System registers, see Chapter G8 AArch32 System Register Descriptions.

___ Note ___

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See for example, ERET on page F5-3933.
G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of \( n \) indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-2276 provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within Security states. The ARMv8-A security model on page G1-5215 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter G5 The AArch32 Virtual Memory System Architecture.

G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- **EL0**: Applications.
- **EL1**: OS kernel and associated functions that are typically described as privileged.
- **EL2**: Hypervisor.
- **EL3**: Secure monitor.
G1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

- Terminology for taking an exception.
- Terminology for returning from an exception.
- Exception levels.
- Definition of a precise exception.
- Definitions of synchronous and asynchronous exceptions on page G1-5211.

G1.3.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is taken from. The PE state immediately after taking the exception is the state that the exception is taken to.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state that the exception returns to.

G1.3.3 Exception levels

An Exception level, EL_n, with a larger value of n than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of n than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
- Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt all exceptions that are taken to AArch32 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address that is used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

--- Note ---

- For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page E2-3559.
- The SError interrupt replaces the ARMv7 asynchronous abort.
G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as **synchronous** if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as **asynchronous** if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-5239.
G1.4 Execution state

The Execution states are:

- **AArch64**: The 64-bit Execution state.
- **AArch32**: The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

*Execution state on page A1-36* gives more information about them.

Exception levels use Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

**Note**

- *Typical Exception level usage model on page G1-5209* shows which Exception levels different software layers might typically use.
- *The effect of implementation choices on the programmers’ model on page D1-2276* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-2263* describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of PE modes that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in *AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-5227*.

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ, and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in *Security state on page G1-5215*.
- User mode. This mode always executes at EL0.

**Note**

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32 state.

For more information on modes, see *AArch32 state PE mode descriptions on page G1-5222*.

The mode in use immediately before an exception is taken is described as the mode the exception is taken from. The mode that is used on taking the exception is described as the mode the exception is taken to.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2 and EL3.
Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the default mode for that exception.

In AArch32 state, a number of different modes can exist at the same Exception level. All modes at a particular Exception level have the execution privilege, meaning they have the same access rights for accesses to memory and to System registers. However, the mapping of PE modes to Exception levels depends on the Security state, as described in Security state on page G1-5215. Security state, Exception levels, and AArch32 execution privilege on page G1-5218 gives more information about the PE modes, their associated execution privilege, and how this maps onto the Exception levels.
G1.5 Instruction Set state

In AArch32 state, the Instruction Set state determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

**T32 state** The PE is executing T32 instructions.

**A32 state** The PE is executing A32 instructions.

--- Note ---

In previous versions of the ARM architecture:

• The T32 instruction set was called the Thumb instruction set.
• The A32 instruction set was called the ARM instruction set.

---

For more information, see Process state, PSTATE on page E1-3535.
The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**  
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**  
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About VMSAv8-32* on page G5-5456.

### G1.6.1 The ARMv8-A security model

The principles of the ARMv8-A security model are defined in *The ARMv8-A security model* on page D1-2150.

#### The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and execution privilege.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same execution privilege.

In Secure state:
- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.

- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3.
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.

See *Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64* on page G1-5250 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has the lowest possible execution privilege.

Hyp mode always executes in Non-secure state at EL2 and has higher execution privilege than all of:
- User mode.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode.
Limited use of Privilege level in ARMv8 AArch32 state on page G1-5219 describes how, in some contexts, the concept of Privilege levels can be used to represent the execution privilege hierarchy.

For more information about the modes, see About the AArch32 PE modes on page G1-5212.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

![Figure G1-1 ARMv8-A Security model when EL3 is using AArch32](image)

Note

For an overview of the Security models when EL3 is using AArch64:

- See Figure G1-2 on page G1-5225 for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See Figure D1-1 on page D1-2151 for an overview of the set of possible implementations.

Figure G1-1 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

**Secure state**

<table>
<thead>
<tr>
<th>EL0</th>
<th>User mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3</td>
<td>Any mode that is available in Secure state, other than User mode.</td>
</tr>
</tbody>
</table>

**Non-secure state**

<table>
<thead>
<tr>
<th>EL0</th>
<th>User mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL1</td>
<td>Any mode that is available in Non-secure state, other than Hyp mode and User mode.</td>
</tr>
<tr>
<td>EL2</td>
<td>Hyp mode.</td>
</tr>
</tbody>
</table>

Execution at EL0 is described as **unprivileged execution**.
A mode associated with a particular Exception level, ELn, is described as an ELn mode.

--- Note ---

The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

---

When EL3 is using AArch32, many AArch32 System registers accessible at PL1 are banked between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, System registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1-accessible System registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 System registers in an interprocessing environment, see **Mapping of the System registers between the Execution states** on page D1-2266.

For more information on the System registers, see **The AArch32 System register interface** on page G1-5305.

The Secure Monitor Call (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see **Secure Monitor Call (SMC) exception** on page G1-5279 and **SMC** on page F5-4257.

--- Note ---

For more information about the Privilege level terminology, see **Security state, Exception levels, and AArch32 execution privilege** on page G1-5218.

---

**Changing from Secure state to Non-secure state**

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the SCR.NS bit, when EL3 is using AArch32.
- By the SCR_EL3.NS bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to Non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while SCR.NS is 1.
- Using an MCR instruction that writes SCR.NS to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to Non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.
G1.7 Security state, Exception levels, and AArch32 execution privilege

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G1-1 shows this hierarchy for each Security state.

Table G1-1 Execution privilege and Exception levels, by Security state

<table>
<thead>
<tr>
<th>Execution privilege</th>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Typical use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>
<td>EL3</td>
<td>-a</td>
<td>Secure monitor</td>
</tr>
<tr>
<td>-</td>
<td>EL2b</td>
<td>EL2</td>
<td>Hypervisor</td>
</tr>
<tr>
<td>-</td>
<td>EL1</td>
<td>EL1</td>
<td>Secure or Non-secure OS</td>
</tr>
<tr>
<td>Lowest, Unprivileged</td>
<td>EL0</td>
<td>EL0</td>
<td>Secure or Non-secure application</td>
</tr>
</tbody>
</table>

a. EL3 is never implemented in Non-secure state.

b. If ARMv8.4-SecEL2 is implemented and enabled in AArch64 state, EL2 can be enabled in Secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current PE mode. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-5216 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-5225 shows this mapping when EL3 is using AArch64.

Table G1-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state: If either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state: If EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

Table G1-2 Mapping of AArch32 PE modes to Exception levels

<table>
<thead>
<tr>
<th>Exception level</th>
<th>PE modes in the given Security state, and EL3 Execution state</th>
<th>Secure state, EL3 using AArch32</th>
<th>Secure state, EL3 using AArch64a</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3</td>
<td>Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>-</td>
<td>-</td>
<td></td>
</tr>
<tr>
<td>EL2</td>
<td>-</td>
<td>-</td>
<td>Hyp</td>
<td></td>
</tr>
<tr>
<td>EL1</td>
<td>-</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td></td>
</tr>
<tr>
<td>EL0</td>
<td>User</td>
<td>User</td>
<td>User</td>
<td></td>
</tr>
</tbody>
</table>

a. If ARMv8.4-SecEL2 is implemented and enabled in AArch64 State, this column can be applied to EL2.

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.
G1.7.1 Limited use of Privilege level in ARMv8 AArch32 state

As described in The VMSAv8-32 translation regimes on page G5-5458, a translation regime maps a virtual address (VA) to the corresponding physical address (PA). The VMSAv8-64 translation regimes are defined by the Exception levels that use them. However, because the mapping between PE modes and Exception levels in Secure state depends on whether EL3 is using AArch32 or is using AArch64, as shown in Table G1-2 on page G1-5218, the VMSAv8-32 translation regimes cannot be described simply in terms of either the Exception levels or the PE modes that use them.

To provide a consistent description of address translation as seen from AArch32 state, the VMSAv8-32 translation regimes are described in terms of the *Privilege levels* originally defined in the ARMv7 descriptions of AArch32 state. Table G1-3 shows how the PE modes map to these Privilege levels:

<table>
<thead>
<tr>
<th>Privilege level</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL2</td>
<td>-</td>
<td>Hyp&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>PL1</td>
<td>Monitor&lt;sup&gt;b&lt;/sup&gt;, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>PL0</td>
<td>User</td>
<td>User</td>
</tr>
</tbody>
</table>

<sup>a</sup> Implemented only in Non-secure state, and only if EL2 is using AArch32 state.<br>
<sup>b</sup> Implemented only in Secure state, and only if EL3 is using AArch32 state.

Comparing Table G1-3 with Table G1-2 on page G1-5218 shows that:

**In Non-secure state**

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

**In Secure state**

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

- **EL3 using AArch64** Secure PL1 maps to Secure EL1. Monitor mode is not implemented.
- **EL3 using AArch32** Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.
G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the `ERET` instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

--- Note ---

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

In AArch32 state, EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter G5 *The AArch32 Virtual Memory System Architecture*.

G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. *EL2 configurable controls on page G1-5323*, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.
Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See Virtual interrupts.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-5266.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information, see:
  - Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.
  - Routing debug exceptions to EL2 using AArch32 on page G1-5256.
  - Routing of aborts taken to AArch32 state on page G1-5258

- Provides mechanisms to trap PE operations to EL2. See EL2 configurable controls on page G1-5323.

When an operation is trapped to EL2, the hypervisor typically either:

- Emulates the required operation. The application running in the Guest OS is unaware of the trap.
- Returns an error to the Guest OS.

**Virtual interrupts**

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table G1-4.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>External SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example G1-1 shows a usage model for virtual interrupts.

**Example G1-1 Virtual interrupt usage model**

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information, see Virtual exceptions when an implementation includes EL2 on page G1-5266.
G1.9  AArch32 state PE modes, and general-purpose and Special-purpose registers

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- AArch32 state PE mode descriptions.
- AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-5227.
- Saved Program Status Registers (SPSRs) on page G1-5229.
- ELR_hyp on page G1-5230.

Note

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

G1.9.1  AArch32 state PE mode descriptions

Table G1-5 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The **PE mode** column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-5227.
- The **Encoding** column gives the corresponding PSTATE.M field.
- The **Exception level** column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see Exception levels on page G1-5209.

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

<table>
<thead>
<tr>

</tbody>
</table>

\(^a\) EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.
Note

ARMv8.4-SecEL2 is not supported if EL2 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

This section gives more information about each of the modes, when it is implemented.

User mode
Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

• Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
• Makes only unprivileged access to memory.
• Cannot change mode except by causing an exception, see Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239.

System mode
System mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode
Supervisor mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing an SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

Abort mode
Abort mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode
Undefined mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode
FIQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode
IRQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-5224.

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode
Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.
In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.

**Note**

This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

When the value of the Hypervisor Call enable bit, SCR.HCE, is 1, executing an HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see *Hyp mode* on page G1-5225.

**Monitor mode**

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the SCR.NS bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see *PE mode for taking exceptions* on page G1-5249.

When EL3 is using AArch32, software executing in Monitor mode:

- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

**Secure and Non-secure modes**

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:

- If a PE is in Supervisor mode and Secure state, it is in Secure Supervisor mode.
- If a PE is in User mode and Non-secure state, it is in Non-secure User mode.

**Note**

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state.
- Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.

**Effect of the EL3 Execution state on the PE modes and Exception levels**

Figure G1-1 on page G1-5216 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 on page G1-5225 shows how the implemented modes change when EL3 is using AArch64.
Comparing Figure G1-1 on page G1-5216 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

**Non-secure state**
- If Non-secure EL1 is using AArch32, then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

**Secure state**
- If Secure EL1 is using AArch32, then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.
- EL3 using AArch64
  - In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-5216.

**Hyp mode**
Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

---

### Note
The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the SCR_EL3.NS or SCR.NS bit set to 1.
This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see Figure G1-1 on page G1-5216.
- Hyp mode is accessible only in Non-secure state. In Secure state, an attempt by a CPS or an MSR instruction to change PSTATE.M to Hyp mode is an illegal change to PSTATE.M, as described in Illegal changes to PSTATE.M on page G1-5235.
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see ERET on page F5-3933.
- In Hyp mode, the CPACR has no effect on the execution of:
  - System register access instructions.
  - Advanced SIMD and floating-point instructions.
  The HCPTR controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see SVC on page F5-4410.
- An exception return with restored PSTATE specifying Hyp mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5262, if any of the following applies:
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - EL3 is using AArch32 and the value of SCR.NS is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - SRS. See SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4292.
  - RFE. See RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-4189.
  - LDM (exception return) on page F5-3966.
  - LDM (User registers) on page F5-3968.
  - STM (User registers) on page F5-4332.
  - The SUBS PC, LR forms of the instructions described in SUB, SUBS (immediate) on page F5-4394.
  
  ______ Note _______
  In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.
  
  — The exception return form of the instructions described in MOV, MOVs (register) on page F5-4081.
  In addition, deprecated forms of the A32 ADCS, ADDS, ANDS, BICS, EORS, MOVs, MNS, ORRS, RSBS, RCS, SBCS, and SUBS instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.
- The Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are CONSTRAINED UNPREDICTABLE if executed in Hyp mode, see Execution of Load/Store unprivileged instructions in Hyp mode on page K1-7214.

In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:
- By setting the SCR_EL3.HCE bit to 1, if EL3 is using AArch64.
- By setting the SCR.HCE bit to 1, if EL3 is using AArch32.

If EL3 is implemented and using AArch32, and SCR.HCE bit is set to 0, the HVC instruction is UNPREDICTABLE in Hyp mode. The instruction is either UNDEFINED or executes as a NOP.
If EL3 is implemented and using AArch64, and SCR_EL3.HCE bit is set to 0, the HVC instruction is UNDEFINED in Hyp mode.

If EL3 is not implemented and HCR_EL2 or HCR.HCD is set to 1, the HVC instruction is UNDEFINED in Hyp mode.

Pseudocode description of mode operations

The BadMode() function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The BadMode() function is defined in Chapter 11 ARMv8 Pseudocode.

G1.9.2 AArch32 general-purpose registers, the PC, and the Special-purpose registers

The general-purpose registers, and the PC, in AArch32 state on page E1-3533 describes the application level view of the general-purpose registers, and the PC. This view provides:

• The general-purpose registers R0-R14, of which:
  — The preferred name for R13 is SP (stack pointer).
  — The preferred name for R14 is LR (link register).
• The PC, that can be described as R15.

These registers are selected from a larger set of registers, that includes banked copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those Exception levels are using AArch32. Figure G1-3 on page G1-5228 shows the full set of banked general-purpose registers, and the Special-purpose registers:

• The Program Status Registers CPSR and SPSR.
• ELR_hyp.

Note

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.
Figure G1-3 AArch32 general-purpose registers, PC, and Special-purpose registers, showing banking

As described in PE mode for taking exceptions on page G1-5249, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the Special-purpose register ELR_hyp.
  - For the other privileged modes to which exceptions can be taken, a banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of PSTATE, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition, FIQ mode has banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see The general-purpose registers, and the PC, in AArch32 state on page E1-3533.

AArch32 Special-purpose registers

In AArch32 state, the Special-purpose registers are:

- The CPSR and its view as the APSR.
- The SPSR, including the banked copies SPSR_abt, SPSR_fiq, SPSR_hyp, SPSR_irq, SPSR_mon, SPSR_svc, and SPSR_und.
- The ELR_hyp.
Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, \_R[], indexed by parameter \( n \). This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. \_PC is the Program Counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

\texttt{LookUpRIndex()} looks up the index value, \( n \), for the specified register number and PE mode, using \texttt{RBankSelect()} to evaluates the result.

\texttt{R[]} accesses the specified general-purpose register in the current PE mode, using \texttt{Rmode[]} to access the register, accessing \_R[] if necessary. \texttt{SP} accesses the stack pointer, \texttt{LR} accesses the link register, and \texttt{PC} accesses the Program Counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than \texttt{PC}, which has only a non-assignment form.

\texttt{BranchTo()} performs a branch to the specified address.

The \_R[], \_PC, LR, SP, LookUpRIndex(), RBankSelect(), Rmode[], and BranchTo() functions are defined in Chapter J1 ARMv8 Pseudocode.

### G1.9.3 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in Figure G1.3 on page G1-5228. For example, the SPSR for Monitor mode is called \texttt{SPSR\_mon}.

#### Note

Exceptions cannot be taken to EL0.

When the PE takes an exception, PE state is saved from PSTATE in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Monitor mode, PE state is saved in \texttt{SPSR\_mon}. For more information on PSTATE, see \textit{Process state, PSTATE} on page G1-5231.

#### Note

All \texttt{PSTATE} fields are saved, including those which have no direct read and write access.

Saving the PSTATE fields means the exception handler can:

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
  - \texttt{ERET}.
  - \texttt{LDM}.
  - The Exception return form of the instruction described in MOV, MOV\((\text{register})\) on page F5-4081.
  - The Exception return form of the instruction described in SUB, SUBS\((\text{immediate})\) on page F5-4394.

For example, on returning from Monitor mode, PE state is restored to the state stored in \texttt{SPSR\_mon}. If the exception return is made using the RFE instruction, the PE restores the PE state from an SPSR valued read from memory.

- Examine the value that PSTATE had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are \texttt{UNKNOWN} on reset. Any operation in a Non-secure EL1 or EL0 mode makes \texttt{SPSR\_hyp} unknown. SPSR bits that are defined as \texttt{RES0} on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.

For more information on SPSR, see \textit{SPSR, Saved Program Status Register} on page G8-6002.
Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The \texttt{SPSR[]} function accesses the current SPSR and is common to AArch32 and AArch64 operation.

The \texttt{SPSR\text{\texttt{WriteByInstr}()} function is used by the \texttt{MSR (register)} and \texttt{MSR (immediate)} instructions to update the current SPSR.

The \texttt{SPSR[]} and \texttt{SPSR\text{\texttt{WriteByInstr}()} functions are defined in Chapter J1 \textit{ARMv8 Pseudocode}.

\textbf{G1.9.4 ELR\_hyp}

Hyp mode does not provide its own banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR\_hyp, a 32-bit Special-purpose register implemented for this purpose.

ELR\_hyp can be accessed explicitly only by executing:

\begin{itemize}
  \item An \texttt{MRS} or \texttt{MSR} instruction that targets ELR\_hyp, see:
    \begin{itemize}
      \item \texttt{MRS (Banked register)} on page F5-4098.
      \item \texttt{MSR (Banked register)} on page F5-4102.
    \end{itemize}
\end{itemize}

The \texttt{ERET} instruction uses the value in ELR\_hyp as the return address for the exception. For more information, see \texttt{ERET} on page F5-3933.

Software execution in any Non-secure EL1 or EL0 mode makes ELR\_hyp UNKNOWN.
G1.10 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. ProcState is defined in Chapter J1 ARMv8 Pseudocode.

The PSTATE fields that are meaningful in AArch32 state are:

The Condition flags
- N Negative Condition flag.
- Z Zero Condition flag.
- C Carry Condition flag.
- V Overflow Condition flag.

Process state, PSTATE on page E1-3535 gives more information about these.

The overflow or saturation flag
- Q See Process state, PSTATE on page E1-3535.

The greater than or equal flags

The PE state controls
- J, T Instruction set state. See Process state, PSTATE on page E1-3535. J is RES0. On a reset to AArch32 state, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to:
  - A PL1 mode using AArch32, T is set to SCTLR.TE.
  - EL2 using AArch32, T is set to HSCTLR.TE.
- IT[7:0] IT block state bits. See Process state, PSTATE on page E1-3535. On a reset or taking an exception to AArch32 state, these bits are set to 0.
- E Endianness of data accesses. See Process state, PSTATE on page E1-3535. If an implementation provides both Big-endian and Little-endian support, then:
  - On a reset to AArch32 state this bit is set to the IMPLEMENTATION DEFINED reset value of:
    - SCTLR.EE if the highest implemented Exception level is not EL2.
    - HSCTLR.EE if the highest implemented Exception level is EL2.
  - On taking an exception to:
    - A PL1 mode using AArch32, this bit is set to SCTLR.EE.
    - EL2 using AArch32, this bit is set to HSCTLR.EE
- IL Illegal Execution state bit. See The Illegal Execution state exception on page G1-5264. On a reset or taking an exception to AArch32 state, this bit is set to 0.

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see Accessing the PE state controls and the Execution state bit on page G1-5234.

The asynchronous exception mask bits
- A SError interrupt mask bit.
- I IRQ interrupt mask bit.
- F FIQ interrupt mask bit.
For each bit, the values are:

0  Exception not masked.
1  Exception masked.

On a reset to AArch32 state, these bits are set to 1.

On taking an exception to AArch32 state, one or more of these bits are set to 1.

For more information, see both:

- Asynchronous exception masking controls on page G1-5269.
- PE state on exception entry on page G1-5252.

### The mode bits

**M[4:0]**  Current mode of the PE. Table G1-5 on page G1-5222 lists the permitted values of this field. All other values are reserved. [Illegal changes to PSTATE.M on page G1-5235](#) describes the effect of setting M[4:0] to a reserved value.

M[4] is:

**M[4], Execution state**

The current Execution state:

0  AArch64 state.
1  AArch32 state.

Note

This is consistent with the use of M[4:0] in previous versions of the architecture.

On a reset to AArch32 state, M[4:0] is set to:

- 0b10011, meaning Supervisor mode, if the highest implemented Exception level is not EL2.
- 0b11010, meaning Hyp mode, if the highest implemented Exception level is EL2.

On taking an exception to AArch32 state, M[4:0] is set to the target mode for the exception type.

For more information about the PE modes, see:

- [AArch32 state PE mode descriptions on page G1-5222](#).
- [PE state on exception entry on page G1-5252](#).

### Access control bits, from ARMv8.1

**PAN**  Privileged Access Never (PAN) state bit, see About the PAN bit on page G5-5505.

### Timing control bits

**DIT**  Data Independent Timing (DIT) bit. For more information, see About the DIT bit on page E1-3540.

This bit is implemented only when ARMv8.4-DIT is implemented.

On a reset to AArch32 state, this bit is set to 0.

---

**G1.10.1 Accessing PSTATE fields**

The PSTATE fields can be accessed as described in the following subsections:

- [The Current Program Status Register, CPSR on page G1-5233](#).
- [Accessing the PE state controls and the Execution state bit on page G1-5234](#).
- [The CPS instruction on page G1-5234](#).
- [The SETEND instruction on page G1-5234](#).
- [The SETPAN instruction on page G1-5235](#).
The Current Program Status Register, CPSR

Some PSTATE fields can be accessed using the Special-purpose Current Program Status Register (CPSR). The CPSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

The CPSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>27</td>
<td>Q, bit [27]</td>
</tr>
<tr>
<td>26:23, 20, 15:10, 5</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 22  | Bit[22] | In ARMv8.0, Reserved, RES0.  
In ARMv8.1, Privileged Access Never (PAN) state bit, see About the PAN bit on page G5-5505. |
| 21  | DIT, bit [21] | Shows the value of CPSR.DIT immediately before the exception was taken. |
| 4:0 | M[4:0], bits [4:0] | The PSTATE mode bits. |

The other PSTATE fields cannot be accessed by using the CPSR. For information on how to access them, see Accessing the PE state controls and the Execution state bit on page G1-5234.

The application level alias for the CPSR is the APSR. The APSR is a subset of the CPSR. See The Application Program Status Register, APSR on page E1-3537.

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to PSTATE.M can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
• Guaranteed to be visible to any memory access caused by fetching any instruction after the next Context synchronization event in the execution stream.

• Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See Exception return to an Exception level using AArch32 on page G1-5261 for the definition of exception return instructions.

Accessing the PE state controls and the Execution state bit

The PE state controls are the PSTATE.{IL, IT[7:0], J, E, T} fields. Software can read or write these in an SPSR.

In the CPSR:

• The PE state controls, other than PSTATE.E, are RAZ when read by an MRS instruction.

• Writes to the PE state controls, other than PSTATE.E, by MSR (register) or MSR (immediate), are ignored in all modes.

Instructions other than MRS, MSR (register), or MSR (immediate) that access the PE state controls can read and write them in any mode.

Unlike the other PSTATE PE state controls, PSTATE.E can be read by an MRS instruction and might be written by MSR (register) or MSR (immediate). However, ARM deprecates PSTATE.E having a different value from the equivalent System register EE bit, see Mixed-endian support on page G4-5424.

Note

To determine the current endianness, software can use an LDR instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an LDR instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:

• 0x00000001 if the current endianness is little-endian.

• 0x01000000 if the current endianness is big-endian.

The PSTATE.M[4] bit is the Execution state bit. When read by an MRS instruction in AArch32 state, this bit always reads as 1. When written by an MSR (register) instruction or MSR (immediate) instruction, writing a value other than 1 is an illegal change to the PSTATE.M field. See Illegal changes to PSTATE.M on page G1-5235.

The CPS instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.{A, I, F} and PSTATE.M:

CPSIE <iflags> {, #<mode>}  
Sets the specified PSTATE. {A, I, F} exception masks to 0, enabling the exception, and optionally changes to the specified mode.

CPSID <iflags> {, #<mode>}  
Sets the specified PSTATE. {A, I, F} exception masks to 1, disabling the exception, and optionally changes to the specified mode.

CPS #<mode>  
Changes to the specified mode without affecting the PSTATE. {A, I, F} exception masks.

The CPS instruction is unconditional. For more information, see CPS, CPSID, CPSIE on page F5-3902.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

SETEND BE  
Sets PSTATE.E to 1, for big-endian operation.

SETEND LE  
Sets PSTATE.E to 0, for little-endian operation.
The **SETEND** instruction is unconditional. For more information, see **SETEND** on page F5-4239. ARM deprecates use of the **SETEND** instruction.

### The **SETPAN** Instruction

ARMv8.1-PAN adds the **SETPAN** instruction to the A32 and T32 instruction sets, to manipulate **PSTATE.PAN**:

**SETPAN #0**  
Sets **PSTATE.PAN** to 0, disabling Privileged access-never operation.

**SETPAN #1**  
Sets **PSTATE.PAN** to 1, enabling Privileged access-never operation.

The **SETPAN** instruction is unconditional.

- **SETPAN** on page F5-4240.
- **About the PAN bit** on page G5-5505.

### G1.10.2 The Saved Program Status Registers (SPSRs)

On taking an exception, **PSTATE** is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in **Saved Program Status Registers (SPSRs)** on page G1-5229.

### G1.10.3 Illegal changes to **PSTATE.M**

In AArch32 PE modes other than User mode, MSR and CPS instructions can explicitly change **PSTATE.M**. The following changes to **PSTATE.M** by MSR or CPS instructions are illegal:

- A change to an encoding that Table G1-5 on page G1-5222 does not show.
- A change to a mode that is not implemented.
- A change to a mode that is not accessible from the context the MSR or CPS instruction is executed in, as follows:
  - A change to a mode that would cause entry to a higher Exception level.
  - When executing in Non-secure state, a change to Monitor mode.
  - When executing in Secure EL1, a change to Monitor mode when EL3 is using AArch64.
  - A change to Hyp mode from any other mode.
  - A change from Hyp mode to any other mode.
  - When the value of **HCR.TGE** is 1, attempting to change from Monitor mode to a Non-secure PL1 mode, see **Trapping of general exceptions to Hyp mode** on page K1-7215.

On executing an instruction that attempts an illegal change to **PSTATE.M**:

- **PSTATE.M** is unchanged, and the current mode remains unchanged.
- **PSTATE.IL** is set to 1.
- All other **PSTATE** fields are written to as normal.

**Note**

For the **PSTATE** fields that MSR and CPS instructions update, see the instruction descriptions:

- **MSR (register)** on page F5-4108.
- **MSR (immediate)** on page F5-4106.
- **CPS, CPSID, CPSIE** on page F5-3902.

When the value of **PSTATE.IL** is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See **The Illegal Execution state exception** on page G1-5264.

**Note**

- The PE ignores writes to **PSTATE.M** when executing at PL0.
- In ARMv7, an instruction that attempts to make an illegal change to **PSTATE.M** is UNPREDICTABLE.
G1.10.4 Pseudocode description of PSTATE operations

The `CPSRWriteByInstr()` function is used by the MSR (register) and MSR (immediate) instructions to update PSTATE.

The `SetPSTATEFromPSR()` function updates PSTATE from a CPSR or SPSR.

Chapter J1 ARMv8 Pseudocode defines these functions.
G1.11 Instruction set states

The instruction set states are described in Chapter E2 The AArch32 Application Level Memory Model and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- Exceptions and instruction set state.
- Unimplemented instruction sets.

G1.11.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the SCTLR.TE bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of HSCTLR.TE.
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE. If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry, see Overview of exception entry on page G1-5246.

G1.11.2 Unimplemented instruction sets

The PSTATE.T bit defines the current instruction set state, see Process state, PSTATE on page E1-3535.

In the ARMv8 architecture, there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in Trivial implementation of the Jazelle extension.

Note

In previous versions of the ARM architecture, the PSTATE.{J, T} bits determined the Instruction set state. In ARMv8, PSTATE.J is RES0.

Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1, EL2, or EL3, if the Exception level is using AArch32:
  - The JMCR and JOSCR are RAZ/WI.
  - The JIDR is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
  - It is IMPLEMENTATION DEFINED whether the JMCR and JOSCR are RAZ/WI or UNDEFINED.
  - It is IMPLEMENTATION DEFINED whether JIDR is RAZ or UNDEFINED.
- The BXJ instruction behaves identically to the BX instruction in all circumstances.

Note

This is consistent with the JMCR.JE bit being RAZ, and means that the A32 and T32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.
• Jazelle state, as defined in previous versions of the ARM architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly.

A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

--- Note ---

This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.
G1.12 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- Exception vectors and the exception base address.
- Exception prioritization for exceptions taken to AArch32 state on page G1-5242.
- Overview of exception entry on page G1-5246.
- PE mode for taking exceptions on page G1-5249.
- PE state on exception entry on page G1-5252.
- Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.
- Routing debug exceptions to EL2 using AArch32 on page G1-5256.

See also:

- Routing of aborts taken to AArch32 state on page G1-5258.
- Exception return to an Exception level using AArch32 on page G1-5261.
- Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-5266.
- AArch32 state exception descriptions on page G1-5274.

G1.12.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the exception vector for that exception. The vectors for the different types of exception form a vector table.

--- Note ---

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32.

When an exception is taken to an Exception level that is using AArch64, then the exception is taken as described in Chapter D1 The AArch64 System Level Programmers’ Model using the exception vectors described in Exception vectors on page D1-2171.

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

---

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an exception base address. These eight vectors form an AArch32 vector table.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.
Note

Exceptions cannot be taken to System mode.

For this vector table:

- When SCTLR.V == 0, the VBAR holds the exception base address.
- When SCTLR.V == 1, the exception base address is 0xFFFF0000.

Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.
  For this vector table, HVBAR holds the exception base address.

Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.
  For this vector table, MVBAR holds the exception base address.
- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.
  - When the Secure instance of SCTLR.V == 0, the Secure instance of VBAR holds the exception base address.
  - When the Secure instance of SCTLR.V == 1, the exception base address is 0xFFFF0000.
- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.
  - When the Non-secure instance of SCTLR.V == 0, the Non-secure instance of VBAR holds the exception base address.
  - When the Non-secure instance of SCTLR.V == 1, the exception base address is 0xFFFF0000.

The following subsections give more information:

- The vector tables and exception offsets.
- Pseudocode determination of the exception base address on page G1-5242.

The vector tables and exception offsets

Table G1-6 on page G1-5241 defines the AArch32 vector table entries. In this table:

- The Hyp column defines the vector table entries for exceptions taken to Hyp mode.
- The Monitor column defines the vector table entries for exceptions taken to Monitor mode.
- The Secure and Non-secure columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-7 on page G1-5241 shows the mode to which each of these exceptions is taken. Each of these modes is described as the default mode for taking the corresponding exception.

Note

Exceptions cannot be taken to System mode or User mode.
For more information about determining the mode to which an exception is taken, see PE mode for taking exceptions on page G1-5249.

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see Interrupt offsets of AArch32 exceptions provided by EL2 on page G1-5242.

a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table.
d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. In ARMv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
e. See Use of offset 0x14 in the Hyp vector table on page G1-5242.

For more information about use of the vector tables, see Overview of exception entry on page G1-5246.
Interrupt offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in Table G1-6 on page G1-5241:

Hypervisor Call
If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see Use of offset 0x14 in the Hyp vector table.

Hyp Trap
Shown explicitly in the Hyp mode vector table.

Virtual Abort
Entered through the Data Abort vector in the Non-secure vector table.

Virtual IRQ
Entered through the IRQ vector in the Non-secure vector table.

Virtual FIQ
Entered through the FIQ vector in the Non-secure vector table.

Note
Virtual exceptions when an implementation includes EL2 on page G1-5266 gives more information about the virtual exceptions.

Use of offset 0x14 in the Hyp vector table

The vector at offset 0x14 in the Hyp vector table is used for all exceptions that cause entry to Hyp mode from Non-secure EL0 and EL1, except for IRQ and FIQ exceptions.

Note
Virtual exceptions are never taken to Hyp mode.

Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the ExcVectorBase() function determines the exception base address.

The ExcVectorBase() function is defined in Chapter J1 ARMv8 Pseudocode.

Note
The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see Security state, Exception levels, and AArch32 execution privilege on page G1-5218.

G1.12.2 Exception prioritization for exceptions taken to AArch32 state

The following sections describe the ARMv8 requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5243.
- Architectural requirements for taking asynchronous exceptions on page G1-5245.

See also:

- AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5555, for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation.
- Debug state entry and debug event prioritization on page H2-6419 for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.
Synchronous exception prioritization for exceptions taken to AArch32 state

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

--- Note ---

- An exception that is taken to an Exception level that is using AArch32 must have been taken from an Exception level that is using AArch32.
- The priority numbering in this list correlates with the equivalent AArch64 list in Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.

For an exception that is taken to an Exception level that is using AArch32, exceptions are prioritized as follows, where 1 is the highest priority.

1-5 These priority numbers are used by AArch64 exceptions or debug events.

6 PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:
   - The CONSTRAINED UNPREDICTABLE handling of a branch to an unaligned address, see Branching to an unaligned PC on page K1-7196.
   - Exiting from Debug state to AArch32 specifying an unaligned PC value, see Exiting Debug state on page H2-6452.

   A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-5282.

7 Prefetch Abort exceptions. See Prefetch Abort exception on page G1-5281 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5555.

8 Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
   - Breakpoint exceptions on page G2-5366.
   - Vector Catch exceptions on page G2-5405.

--- Note ---

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

9 Illegal Execution state exceptions. See The Illegal Execution state exception on page G1-5264.

10 Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
   - HSTR.Tn.
   - HCR.TIDCP.

11 Software Breakpoint Exceptions caused by the execution of a BKPT Exception generating instruction.

12 Undefined Instruction exceptions that occur as a result of one or more of the following:
   - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
   - Debug state execution of an instruction encoding that is unallocated in Debug state.
   - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
   - Execution of an HVC instruction, when HVC instructions are disabled by SCR.HCE or HCR.HCD.
- Execution of an HLT instruction when HLT instructions are disabled by EDSCR.HDE or when halting is prohibited.
- In Debug state:
  - Execution of a DCPS1 instruction in Non-secure EL0 when HCR.TGE is 1.
  - Execution of a DCPS2 instruction in EL1 or EL0 when SCR.NS is 0 or when EL2 is disabled or not implemented in the current Security state.
  - Execution of a DCPS3 instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
  - When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
- Execution of an instruction that is UNDEFINED as a result of any of:
  - Being in an IT block when SCTLR.ITD is 1, or when HSCTLR.ITD is 1.
  - Executing a SETEND instruction when SCTLR.SED is 1, or when HSCTLR.SED is 1.
  - Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTLR.CP15BEN is 0, or when HSCTLR.CP15BEN is 0.
- Execution of an instruction that is UNDEFINED because at least one of FPSCR.{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exceptions and exception traps on page G1-5312.

Exceptions taken to EL1, or taken to EL2 because of the value of HCR.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 6-12.

Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
- HSTR.Tn.
- HCR.TIDCP.

Exceptions taken to EL2 because of configuration settings in the HCPTR.

Exceptions taken to EL2 because of one of the following configuration settings:
- Any setting in HCR, other than the TIDCP bit.
- Any setting in CNTHCTL.
- Any setting in HDCR.

Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 6-16.

Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR.SCD is 1.

Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, or SMC.

These priority numbers are used by AArch64 exceptions.

Exceptions taken to EL3 from EL0, EL1 or EL2 because of configuration settings in the SDCR.

Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 6-22.

Trapped floating-point exceptions, if supported. See Floating-point exceptions and exception traps on page G1-5312.

These priority numbers are used by AArch64 exceptions and debug events.
Data Abort exceptions other than a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 29. See Data Abort exception on page G1-5285 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5555. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 29.

Watchpoint exceptions. See Watchpoint exceptions on page G2-5391.

Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk, see External aborts on page G4-5449. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 27.

For items 27-29, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

Note

Exceptions generated by a translation table walk are reported and prioritized as either a Prefetch Abort exception, priority 7 in this list, or a Data Abort exception, priority 27 in this list. See also AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5555.

Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked:

- Execution of an ISB instruction that does not fail its Condition code check.
- Exception entry.
- Exception return.
- Exit from Debug state.

Note

If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.

- The ISR identifies any pending asynchronous exceptions.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

Note

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken, then it must be taken before the first Context synchronization event after the interrupt was changed to not pending.
**PSTATE** includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-5266.

Taking an exception sets an exception-dependent subset of these mask bits.

---

Note

In some contexts, the **PSTATE.**{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in **PSTATE.**{A, I, F, M} values on exception entry on page G1-5253, can prevent an exception handler being interrupted by an asynchronous exception.

---

**G1.12.3 Overview of exception entry**

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see *PE mode for taking exceptions* on page G1-5249.
2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
   - The exception type.
   - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
   - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

   Where the link value is saved depends on whether the exception is taken to the EL2 mode.

   For more information, see *Link values saved on exception entry* on page G1-5247.
3. The value of **PSTATE** is saved in the SPSR for the mode to which the exception must be taken. The value saved in SPSR.IT[7:0] is always correct for the preferred return address.
4. In an implementation that includes EL3, when EL3 is using AArch32:
   - If the exception is taken from Monitor mode, SCR.NS is cleared to 0.
   - Otherwise, taking the exception leaves SCR.NS unchanged.

   When EL3 is using AArch64, Monitor mode is not available.
5. **PSTATE** is updated with new context information for the exception handler. This includes:
   - Setting **PSTATE.**M to the PE mode to which the exception is taken.
   - Setting the appropriate **PSTATE** mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
   - Setting the instruction set state to the state required for exception entry.
   - Setting the endianness to the required value for exception entry.
   - Clearing the **PSTATE.**IT[7:0] bits to 0.

   For more information, see *PE state on exception entry* on page G1-5252.
6. The appropriate exception vector is loaded into the PC, see *Exception vectors and the exception base address* on page G1-5239.
7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see *SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-4292 and *CPS, CPSID, CPSIE* on page F5-3902.
Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-8 gives an index to these descriptions:

Table G1-8 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state

G1 The AArch32 System Level Programmers’ Model
G1.12 Handling exceptions that are taken to an Exception level using AArch32

Note
• Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
• For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

Exception taken to a non-EL2 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table G1-10 shows:

Table G1-9 Exception return addresses for exceptions taken to AArch32 state (continued)

<table>
<thead>
<tr>
<th>Exception</th>
<th>Preferred return address</th>
<th>Taken to a mode at</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>IRQ or FIQ</td>
<td>Address of next instruction to execute</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Virtual IRQ or Virtual FIQ</td>
<td>Address of next instruction to execute</td>
<td>EL1, and only in Non-secure state</td>
</tr>
</tbody>
</table>

a. EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.
b. A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.
c. EL2 is implemented only in Non-secure state when using AArch32 state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state when using AArch32 state.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

Exception taken to an EL2 mode

The link value is saved in the ELR\(_\text{hyp}\) Special-purpose register.

Table G1-10 Offsets applied to Link value for exceptions taken to non-EL2 modes

<table>
<thead>

</table>
The saved link value is the preferred return address for the exception, as shown in Table G1-9 on page G1-5247, with no offset.

**G1.12.4 PE mode for taking exceptions**

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:

- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.

- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

**In an implementation that does not include EL2 or EL3**

An exception is always taken to the default mode for that exception.

**In an implementation that includes EL3**

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64, then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32* on page G1-5250.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode. Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Security state, Exception levels, and AArch32 execution privilege* on page G1-5218, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

**In an implementation that includes EL2**

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode, then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode* on page G1-5250, or taken to the default mode for the exception.

**Note**

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- Hyp mode has no effect on the handling of exceptions taken from Secure state.

Table G1-7 on page G1-5241 shows the default mode to which each exception is taken.

*Asynchronous exception routing controls* on page G1-5268 describes the exception routing controls provided by EL2 and EL3.
Routing of aborts taken to AArch32 state on page G1-5258 gives more information about the modes to which memory aborts are taken.

The possible modes for taking each exception on page G1-5251 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3.
- That do not include EL2 but include EL3.
- That include both EL2 and EL3.

Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in Asynchronous exception routing controls on page G1-5268, is taken to Hyp mode.

- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  - An abort that Routing of aborts taken to AArch32 state on page G1-5258 identifies as taken to Hyp mode.
  - A Hyp Trap exception, see EL2 configurable controls on page G1-5323.
  - A Hypervisor Call exception. This is generated by executing an HVC instruction in a Non-secure mode.
  - An SError interrupt exception, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in Asynchronous exception routing controls on page G1-5268.
  - A synchronous External abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

--- Note ---
A synchronous External abort can be routed to Hyp mode only if it is not routed to EL3.

--- Note ---
A debug exception that is explicitly routed to Hyp mode as described in Routing debug exceptions to EL2 using AArch32 on page G1-5256.

--- Note ---
The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64

As described in The ARMv8-A security model on page G1-5215, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- Execution of an SMC instruction from a privileged Exception level that is using AArch32
- Non-secure reads of the NSACR on page G1-5251
- Secure EL1 operations when Secure EL1 is using AArch32 state on page G1-5251

Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see ISS encoding for an exception from SMC instruction execution in AArch32 state on page D12-2786.
**Non-secure reads of the NSACR**

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of \(0x00000C00\) in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

**Secure EL1 operations when Secure EL1 is using AArch32 state**

When Secure EL1 is using AArch32 and if ARMv8.4-SecEL2 is implemented and enabled or EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the SCR, NSACR, MVBAR, and SDCR.
  - Executing any of the ATS12NSO** instructions.
  - Executing an SRS instruction that would use SP_mon, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4292.
  - Executing an MSR (banked register) or MSR (banked register) instruction that would access SPSR_mon, SP_mon, or LR_mon, see MRS (Banked register) on page F5-4098 and MSR (Banked register) on page F5-4102.

For more information about these traps, including the associated exception syndromes, see Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2243.

- Any attempt to move into Hypervisor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal return events from AArch32 state on page G1-5262.

- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal return events from AArch32 state on page G1-5262.

---

**Note**

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

---

**The possible modes for taking each exception**

Each of the exception descriptions in AArch32 state exception descriptions on page G1-5274 includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- The PE mode to which the Undefined Instruction exception is taken on page G1-5275.
- The PE mode to which the Hyp Trap exception is taken on page G1-5278.
- The PE mode to which the Monitor Trap exception is taken on page G1-5277.
- The PE mode to which the Supervisor Call exception is taken on page G1-5278.
- The PE mode to which the Secure Monitor Call exception is taken on page G1-5280.
- The PE mode to which the Hypervisor Call exception is taken on page G1-5281.
- The PE mode to which the Prefetch Abort exception is taken on page G1-5283.
- The PE mode to which the Data Abort exception is taken on page G1-5286.
- The PE mode to which the Virtual SError interrupt exception is taken on page G1-5290.
- The PE mode to which the physical IRQ exception is taken on page G1-5291.
- The PE mode to which the Virtual IRQ exception is taken on page G1-5292.
- The PE mode to which the physical FIQ exception is taken on page G1-5293.
- The PE mode to which the Virtual FIQ exception is taken on page G1-5294.
These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- HCR, rather than HCR_EL2, controls the routing of exceptions to EL2.
- SCR, rather than SCR_EL3, controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see *Exception vectors and the exception base address* on page G1-5239.
- The routing of synchronous External aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see *Asynchronous exception routing controls* on page G1-5268.

**UNPREDICTABLE cases when the value of HCR.TGE is 1**

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see *Routing exceptions from Non-secure EL0 to EL2* on page G1-5254. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see *Illegal return events from AArch32 state* on page G1-5262.
- An illegal PE mode change, see *Illegal changes to PSTATE.M* on page G1-5235.

### G1.12.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as Table G1-8 on page G1-5247 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- Instruction set state on exception entry.
- PSTATE.E value on exception entry on page G1-5253.
- PSTATE.{A, I, F, M} values on exception entry on page G1-5253.

**Note**

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the HSCTLR are provided by the SCTLR_EL2.
  - Controls shown as provided by the HCR are provided by the HCR_EL2.
- If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR_EL3.

#### Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, PSTATE.T is set to the required value, as determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. Table G1-11 shows this:

<table>
<thead>
<tr>
<th>Mode to which exception is taken</th>
<th>HSCTLR.TE</th>
<th>SCTLR.TE</th>
<th>PSTATE.T</th>
<th>Exception handler state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Hyp mode</td>
<td>x</td>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>1</td>
<td>T32</td>
</tr>
<tr>
<td>Hyp mode</td>
<td>0</td>
<td>x</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>x</td>
<td>1</td>
<td>T32</td>
</tr>
</tbody>
</table>
When an implementation includes EL3 and EL3 is using AArch32, SCTLR is banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a PE mode other than Hyp mode, the SCTLR.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the instruction set state in which an exception handler might execute depends on the Security state to which the exception is taken.

**PSTATE.E value on exception entry**

PSTATE.E controls the load and store endianness for data handling. Table G1-12 show the value to which this bit is set on exception entry:

<table>
<thead>
<tr>
<th>Exception mode</th>
<th>HSCTL.R.EE</th>
<th>SCTLR.R.EE</th>
<th>Endianness for data loads and stores</th>
<th>PSTATE.E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure or Non-secure EL1</td>
<td>x</td>
<td>0</td>
<td>Little-endian</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>Big-endian</td>
<td>1</td>
</tr>
<tr>
<td>Hyp</td>
<td>0</td>
<td>x</td>
<td>Little-endian</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>x</td>
<td>Big-endian</td>
<td>1</td>
</tr>
</tbody>
</table>

**PSTATE.{A, I, F, M} values on exception entry**

On exception entry, PSTATE.M is set to the value for the mode to which the exception is taken, as described in PE mode for taking exceptions on page G1-5249.

Table G1-13 shows the cases where PSTATE.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a PSTATE.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The PE mode exception is taken to column is the mode to which the exception is taken.
- The Non-secure column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The Secure column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

<table>
<thead>
<tr>
<th>PE mode exception is taken to</th>

</table>

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-5256 describes how, in some situations, the PSTATE.\{A, I, F\} bits mask the taking of SError interrupts, IRQ interrupts, and FIQ interrupts.

### G1.12.6 Routing exceptions from Non-secure EL0 to EL2

**Note**

The routing control described in this section permits a Non-secure state usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running at Non-secure EL1. This control applies when the PE is executing in Non-secure EL0 using AArch32 and EL2 is using AArch32 and the value of HCR.TGE is 1.

If the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2 if either:

- EL2 is using AArch32 and the value of HCR.TGE is 1.
  - In this case the exception is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. For more information see Exception reporting when HCR.TGE routes an exception to EL2 using AArch32 on page G1-5255.

- EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.
  - In this case the exception is taken to EL2 using AArch64, see Exception entry on page D1-2170.

Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected by the value of HCR.TGE or HCR_EL2.TGE.

When the value of HCR.TGE is 1, meaning TGE routing from Non-secure EL0 using AArch32 to EL2 using AArch32 applies:

- The SCTLR.M bit is treated as 0 for all purposes other than a direct read of the SCTLR register.
- Each of the HCR.\{FMO, IMO, AMO\} bits is treated as 1 for all purposes other than a direct read of the HCR register.
- Each of the HDCR.\{TDE, TDA, TDRA, TDOSA\} bits is treated as 1 for all purposes other than a direct read of the HDCR register.
- An exception return to Non-secure EL1 is treated as an illegal exception return, see Illegal return events from AArch32 state on page G1-5262.
- All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.
Exception reporting when HCR.TGE routes an exception to EL2 using AArch32

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of HCR.TGE is 1:

- **Undefined Instruction exception, when the value of HCR.TGE is 1.**

- **Supervisor Call exception, when the value of HCR.TGE is 1.**

- **Abort exceptions, when the value of HCR.TGE is 1.**

- **Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1 on page G1-5256.**

**Undefined Instruction exception, when the value of HCR.TGE is 1**

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value \(0x00\). For more information see *Use of the HSR* on page G5-5572.

**Supervisor Call exception, when the value of HCR.TGE is 1**

When HCR.TGE is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the \(\text{imm16}\) value in the HSR:
  - A zero-extended 8-bit immediate value for the T32 SVC instruction.
  
  **Note**
  
  The only T32 encoding for SVC is a 16-bit instruction encoding.
  
  — The bottom16 bits of the immediate value for the A32 SVC instruction.

- If the SVC is conditional, the \(\text{imm16}\) value in the HSR is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its Condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value \(0x11\). For more information, see *Use of the HSR* on page G5-5572.

**Note**

The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

**Abort exceptions, when the value of HCR.TGE is 1**

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or to EL3 using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

When SCR.EA is set to 1, External aborts and SError interrupts are routed to EL3, and this routing takes priority over the HCR.TGE routing. For more information, see *Routing of aborts taken to AArch32 state* on page G1-5258.

An SError interrupt that is routed to Hyp mode because the value of HCR.TGE is 1 is reported as a Data Abort exception routed to Hyp mode.

The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value \(0x20\).
- As a Data Abort exception routed to Hyp mode, using the EC value \(0x24\).

For more information about the exception reporting, see *Use of the HSR* on page G5-5572.
Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1

PL1 configurable controls on page G1-5315 describes controls that, when the value of HCR.TGE is 0, can generate exceptions that are taken from Non-secure EL0 to EL1. When EL2 is using AArch32 and the value of HCR.TGE is 1, the exceptions generated by these controls are routed to Hyp mode. Table G1-14 shows how these exceptions are then reported in the HSR.

Table G1-14 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables

a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with Instruction enables and instruction disables on page G1-5314.

G1.12.7 Routing debug exceptions to EL2 using AArch32

When the value of HDCR.TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see Chapter G2 AArch32 Self-hosted Debug.

- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See Watchpoint exceptions on page G2-5391.

When the value of HDCR.TDE is 1, each of the HDCR.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the HDCR register.

Note

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See Breakpoint and Watchpoint debug events on page H2-6418.
- When HDCR.TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.

When a Hyp Trap exception is generated because the value of HDCR.TDE is 1, The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.
For more information see *Use of the HSR* on page G5-5572.
G1.13 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  — Using AArch32. In this case, this chapter describes how the abort is handled.
  — Using AArch64. In this case, Chapter D5 The AArch64 Virtual Memory System Architecture describes how the abort is handled.

For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

Memory aborts taken to Monitor mode

If an implementation includes EL3, when the value of SCR.EA is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes.

Memory aborts taken to Secure Abort mode

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

--- Note ---
The only memory aborts that can be routed to Monitor mode are External aborts.

Memory aborts taken to Hyp mode

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
  — When the PE is in Hyp mode.
  — When the PE is in a Non-secure PL1 or EL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  — When the PE is in Non-secure User mode and HCR.TGE is set to 1. For more information see Abort exceptions, when the value of HCR.TGE is 1 on page G1-5255.
- When the PE is using the Non-secure PL1&0 translation regime:
  — MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  — Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see Stage 2 fault on a stage 1 translation table walk on page G5-5553.
- When the PE is using the Non-secure EL2 translation regime, MMU faults from stage 1 translations.

--- Note ---
The Non-secure EL2 translation regime has only one stage of translation.

- External aborts, if SCR.EA is set to 0 and any of the following applies:
  — The PE was executing in Hyp mode when it took the exception.
The PE was executing in a Non-secure PL1 or EL0 mode when it took the exception, the abort is asynchronous, and HCR.AMO is set to 1. For more information see Asynchronous exception routing controls on page G1-5268.

The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and HCR.TGE is set to 1. For more information see Abort exceptions, when the value of HCR.TGE is 1 on page G1-5255.

The RAS Extension is implemented, the PE was executing in a Non-secure PL1 or EL0 mode when it took the exception, the abort is synchronous, and the value of HCR2.TEA is 1.

The abort occurred on a stage 2 translation table walk.

• Debug exceptions, if HDCR.TDE is set to 1. For more information, see Routing debug exceptions to EL2 using AArch32 on page G1-5256.

Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

• When the PE is in a Non-secure PL1 or EL0 mode, Alignment faults taken for any of the following reasons:
  — SCTLR.A is set to 1.
  — An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  — The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

  Note
  In an implementation that does not include EL2, this case results in a CONSTRAINED UNPREDICTABLE memory access, see Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE on page E2-3581 and Loads and Stores to unaligned locations on page K1-7196.

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of HCR.TGE is 0.

• When the PE is using the Non-secure PL1&0 translation regime, an MMU fault from a stage 1 translation.

• External aborts, if the PE was executing in a Non-secure PL1 or EL0 mode when it took the exception and both:
  — The value of SCR.EA is 0, meaning the abort is not taken to EL3.
  — The abort is not taken to EL2 for one of the reasons defined in Memory aborts taken to Hyp mode.

• Virtual Aborts, see Virtual exceptions when an implementation includes EL2 on page G1-5266.

• When the value of HDCR.TDE is 0, Debug exceptions. For more information, see Routing debug exceptions to EL2 using AArch32 on page G1-5256.

  Note
  If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in Chapter D5 The AArch64 Virtual Memory System Architecture.
Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the SCTLR.A bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239.
G1.14 Exception return to an Exception level using AArch32

In the ARM architecture, exception return to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a preferred return address for each exception other than Reset, see Link values saved on exception entry on page G1-5247. The values of the SPSR.IT[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the PSTATE takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current SPSR at the time of the exception return.

Illegal return events from AArch32 state on page G1-5262 describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

G1.14.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- Return from an exception taken to a PE mode other than Hyp mode.
- Return from an exception taken to Hyp mode on page G1-5262.

Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following exception return instructions:

- From privileged modes other than System mode, the ERET instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which ERET is executed. See ERET on page F5-3933.

- Data-processing instructions with the S bit set and the PC as a destination, see MOV, MOVS (register) on page F5-4081 and SUB, SUBS (immediate) on page F5-4394.

Note

The A32 instruction set includes other instructions that can be used for an exception return, but ARM deprecates any use of those instructions.

Typically:

— A return where no subtraction is required uses SUBS with an operand of 0, or the equivalent MOVS instruction.
A return requiring subtraction uses `SUBS` with a nonzero operand.

- The `RFE` instruction, see `RFE, RFEDA, RFEDB, RFEIA, RFEIB` on page F5-4189. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the `RFE` instruction.

- In A32 state, a form of the `LDM` instruction in which the PC is one of the registers loaded, see `LDM (exception return)` on page F5-3966. If a subtraction is required, typically it is performed before saving the LR value to memory.

**Return from an exception taken to Hyp mode**

For an exception taken to Hyp mode, the ARM architecture provides the `ERET` instruction, see `ERET` on page F5-3933. An exception handler executing in Hyp mode must return using the `ERET` instruction.

Hyp mode is implemented only as part of EL2.

**G1.14.2 Alignment of exception returns**

The T bit of the value transferred to the PSTATE by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the T bit is as follows:

- **T = 0**
  - The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.

- **T = 1**
  - The target instruction set state is T32 state:
    - Bit[0] of the address transferred to the PC is ignored by the hardware.
    - Bit[1] of the address transferred to the PC is part of the instruction address.

**Note**

In previous versions of the ARM architecture, the PSTATE.{J, T} bits determined the Instruction set state. In ARMv8, PSTATE.J is RES0.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the SPSR.T bit. This means that if exception return instructions are used with the LR and SPSR values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

**G1.14.3 Illegal return events from AArch32 state**

Throughout this section:

**Return**

In AArch32 state, refers to any of:
- Execution of any exception return instruction.
- Execution of a `DRPS` instruction in Debug state.
- Exit from Debug state.

If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:
- Zero.
- The value of bit[1] of the return address for the exception or debug return.

The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.
Note

This means software must support both alternatives.

Saved process state value

In AArch32 state, refers to any of:

- The value held in the SPSR for any exception return other than an exception return made by executing an RFE instruction.
- The value read from memory that is to be restored to PSTATE by the execution of an RFE instruction.
- The value held in the SPSR for the execution of a DRPS instruction in Debug state.
- The value held in the DSPSR for a Debug state exit.

Link address

In AArch32 state, refers to any of:

- The address held in the link register for any exception return other than an exception return made by executing an ERET, LDM, or RFE instruction.
- The address held in ELR_hyp for any exception return made by executing an ERET instruction.
- The address read from memory that is to be restored to the PC by the execution of an LDM or RFE instruction.
- The address held in the DLR for Debug state exit.

Configured from reset

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the mode being returned to is not implemented. For example:
  - A return to Hyp mode when EL2 is not implemented.
  - A return to Monitor mode, when EL3 is either not implemented or using AArch64 state.
- A return to EL2 when:
  - EL3 is implemented and using AArch64, and the values of SCR_EL3.{NS, EEL2} are 0.
  - EL3 is implemented and using AArch32, and the value of the SCR.NS bit is 0.
- A return to Non-secure EL1 when:
  - EL2 is implemented and using AArch64, and the value of the HCR_EL2.TGE bit is 1.
  - EL2 is implemented and using AArch32, and the value of the HCR.TGE bit is 1.
- A return where the value of the saved process state M[4:0] field is not a valid AArch32 PE mode for the implementation. Table G1-5 on page G1-5222 shows the valid M[4:0] values for AArch32 PE modes.

In these cases:

- PSTATE_IL is set to 1, to indicate an illegal return.
- PSTATE.M is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see Software Step exceptions on page D2-2329.
- The following PSTATE bits are restored from the saved process state value:
  - The Q Overflow or saturation flag.
--- The GE Greater than or Equal flags.
--- The E Endianness mapping bit.
--- The A, I, F exception mask bits.
--- The DIT Data Independent Timing bit.

• The PSTATE.\{IT, T\} bits are each either:
  — Set to 0.
  — Copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

  The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

• The PC is restored from the link address, unless the illegal return is the execution of a \texttt{DRPS} instruction in Debug state.

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See \textit{The Illegal Execution state exception}.

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

### G1.14.4 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the meaning that is defined in \textit{Illegal return events from AArch32 state} on page G1-5262.

If the IL bit in the saved process state value is 1, then it is copied to PSTATE meaning that PSTATE.IL is set to 1. In this case, the PSTATE.\{IT, T\} bits are each either:

• Set to 0.
• Copied from the SPSR, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the PSTATE.IL bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See \textit{The Illegal Execution state exception}.

### G1.14.5 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the PSTATE.IL bit can be set to 1 by one of the following:

• An illegal return, as described in \textit{Illegal return events from AArch32 state} on page G1-5262.
• An illegal change to PSTATE.M, as described in \textit{Illegal changes to PSTATE.M} on page G1-5235.
• A legal return that sets PSTATE.IL to 1, as described in \textit{Legal returns that set PSTATE.IL to 1}.

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the HSR provides additional syndrome information for the exception, see \textit{Use of the HSR} on page G5-5572.

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.
This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state. The Illegal Execution state exception on page D1-2182 describes the cases where an Illegal Execution state exception is taken to an Exception level that is using AArch64 state.

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the PSTATE.IL bit is 1 and this is copied to the SPSR.IL bit for the PE mode to which the exception is taken.

2. The PSTATE.IL bit is cleared to 0.

This means that it is not possible for software to observe the value of PSTATE.IL.

Pseudocode description of exception return

The AArch32.ExceptionReturn() function transfers the return address to the PC and restores PSTATE to its saved value.

This function uses the function SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.

Chapter J1 ARMv8 Pseudocode includes the definitions of these functions.
G1.15  Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An SError interrupt is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the default PE modes for taking these exceptions.

Note

The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception.

However, the PSTATE.\{A, I, F\} bits mask the asynchronous exceptions, meaning that when the value of one of these PSTATE bits is 1, the corresponding exception is not taken.

If a masked asynchronous exception remains signaled, then the exception remains pending unless the value of the PSTATE bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see Asynchronous exception routing controls on page G1-5268.
- Masking of these exceptions in Non-secure state, see Asynchronous exception masking controls on page G1-5269.

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the HCR when EL2 is using AArch32, and by the HCR_EL2 when EL2 is using AArch64.
- The EL3 controls are provided by the SCR when EL3 is using AArch32, and by the SCR_EL3 when EL3 is using AArch64.

Therefore, most references to the HCR or SCR in this section are to entries in Table K13-1 on page K13-7394, that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-5271.

G1.15.1  Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual SError, that corresponds to a physical external SError interrupt.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of HCR.TGE is 0 and the value of an HCR.\{AMO, IMO, FMO\} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, HCR.\{VA, VI, VF\}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR.
In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual SError is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-15 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Routing the physical exception to EL2</th>
<th>Generating the virtual exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>HCR.AMO</td>
<td>HCR.VA</td>
</tr>
<tr>
<td>IRQ</td>
<td>HCR.IMO</td>
<td>HCR.VI</td>
</tr>
<tr>
<td>FIQ</td>
<td>HCR.FMO</td>
<td>HCR.VF</td>
</tr>
</tbody>
</table>

The HCR.\{VA, VI, VF\} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.\{AMO, IMO, FMO\} is 1.

Similarly, if the implementation also includes EL3, the HCR.\{AMO, IMO, FMO\} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.\{EA, IRQ, FIQ\} bit. For more information, see Asynchronous exception routing controls on page G1-5268.

When the value of an HCR.\{AMO, IMO, FMO\} control bit is 1, the corresponding mask bit in PSTATE:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

---- Note ----

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See WFE wake-up events on page G1-5302 and Wait For Interrupt on page G1-5303 for information about how virtual exceptions affect wake up from power-saving states.

---- Note ----

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

Effects of the HCR.\{AMO, IMO, FMO\} bits

As described in this section, the HCR.\{AMO, IMO, FMO\} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See Asynchronous exception routing controls on page G1-5268.
- Affect the masking of the exceptions. See Asynchronous exception masking controls on page G1-5269.
G1.15.2 Asynchronous exception routing controls

--- Note ---

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-5271.

In an implementation that includes EL3 the following bits in the SCR control the routing of asynchronous exceptions:

**SCR.EA** When the value of this bit is 1, any SError interrupt is taken to EL3.

--- Note ---

Although this section describes the asynchronous exception routing controls, SCR.EA also controls the routing of synchronous External aborts, see Routing of aborts taken to AArch32 state on page G1-5258.

**SCR.FIQ** When the value of this bit is 1, any FIQ exception is taken to EL3.

**SCR.IRQ** When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the SCR.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the HCR route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the SCR.{EA, FIQ, IRQ} controls, to be taken to EL3.

**HCR.AMO** When the value of this bit is 1, an SError interrupt exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of SCR.EA is 0. When the value of SCR.EA is 1, the value of the AMO bit is ignored.

**HCR.FMO** When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.FIQ is 0. When the value of SCR.FIQ is 1, the value of the FMO bit is ignored.

**HCR.IMO** When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.IRQ is 0. When the value of SCR.IRQ is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the HCR.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with SCR.NS set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The HCR.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in Asynchronous exception masking controls on page G1-5269.

The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.
When the PE is in Hyp mode:

- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-5266.

---

### G1.15.3 Asynchronous exception masking controls

---

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-5271.

---

The \texttt{PSTATE.A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- \texttt{PSTATE.A} can mask SError interrupt exceptions.
- \texttt{PSTATE.I} can mask IRQ exceptions.
- \texttt{PSTATE.F} can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the \texttt{HCR, \{AMO, IMO, FMO\}} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the \texttt{SCR, \{AW, FW\}} bits modify the masking of exceptions taken from Non-secure state by the \texttt{PSTATE, \{A, F\}} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the \texttt{PSTATE, \{A, I, F\}} bits. The following subsections describe the masking of these bits in other implementations:

- Asynchronous exception masking in an implementation that includes EL2 but not EL3.
- Asynchronous exception masking in an implementation that includes EL3 but not EL2.
- Asynchronous exception masking in an implementation that includes both EL2 and EL3 on page G1-5270.
- Summary of the asynchronous exception masking controls on page G1-5270.

---

### Asynchronous exception masking in an implementation that includes EL2 but not EL3

The \texttt{HCR, \{AMO, IMO, FMO\}} bits modify the effect of the \texttt{PSTATE, \{A, I, F\}} bits. When the value of an \texttt{HCR, \{AMO, IMO, FMO\}} mask override bit is 1, the value of the corresponding \texttt{PSTATE, \{A, I, F\}} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

---

### Asynchronous exception masking in an implementation that includes EL3 but not EL2

The \texttt{SCR, \{AW, FW\}} bits modify the effect of the \texttt{PSTATE, \{A, F\}} bits. When the value of one of the \texttt{SCR, \{AW, FW\}} bits is 0, the corresponding \texttt{PSTATE, \{A, F\}} bit is ignored when both of the follow apply:

- The corresponding exception is taken from Non-secure state.
- The value of the corresponding \texttt{SCR, \{EA, FIQ\}} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

---

Whenever the value of \texttt{PSTATE.I} is 1, IRQ exceptions are masked and cannot be taken.
Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an HCR.\{AMO, IMO, FMO\} mask override bit is 1, the value of the corresponding PSTATE.\{A, I, F\} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding SCR.\{EA, IRQ, FIQ\} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an SCR.\{AW, FW\} bit is 0, the value of the corresponding PSTATE.\{A, F\} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding SCR.\{EA, FIQ\} bit routes the exception to Monitor mode.
- The corresponding HCR.\{AMO, FMO\} mask override bit is set to 0.

Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the PSTATE.\{A, I, F\} bits. For an implementation that does not include all of the Exception levels:

If the implementation includes only EL1 and EL0

The PSTATE bits cannot be masked. The behavior is as shown in the Secure row of the tables.

If the implementation includes EL2 but not EL3

The behavior is as shown in the Non-secure table rows when the control bits in the SCR are both 0.

If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the HCR is 0.

Table G1-16 shows the controls of the masking of SError interrupt exceptions by PSTATE.A.

**G1.15.4 Asynchronous exception routing and masking with higher Exception levels using AArch64**

*Asynchronous exception routing controls on page G1-5268 and Asynchronous exception masking controls on page G1-5269 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- **Summary of physical interrupt routing.**
- **Summary of physical interrupt masking on page G1-5272.**

**Summary of physical interrupt routing**

The Table G1-19 on page G1-5272 shows the routing of physical FIQ, IRQ and SError interrupts when the highest Exception level is using AArch32. If the highest Exception level is using AArch64, see Table D1-12 on page D1-2199.

In this table:

- **SCR** This is the *Effective value* of a field in SCR.
- **HCR** This is the *Effective value* of a field in HCR.
The Effective value of the field that handles the asynchronous exception type in SCR.

The Effective value of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.

The exception is taken to the FIQ mode, the IRQ mode or the Abort mode according to the type of asynchronous exception.

The exception is taken to AArch32 Hyp mode.

The exception is taken to AArch32 Monitor mode.

This field does not exist, or the Exception level is not accessible in this configuration.

### Summary of physical interrupt masking

Table G1-20 on page G1-5273 shows the masking of physical FIQ, IRQ and SError interrupts when the highest Exception level is using AArch32. When the highest Exception level is using AArch64, see Table D1-15 on page D1-2203.

In this table:

SCR This is the Effective value of a field in SCR.

HCR This is the Effective value of a field in HCR.

FIQ IRQ EA The Effective value of the field that handles the asynchronous exception type in SCR.

FMO IMO AMO The Effective value of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.

FW AW For FIQ interrupts, the SCR_FW field, and for SError interrupts, the SCR_AW field. For IRQ interrupts, there is no equivalent field, so the Effective value is 0 and rows where this cell is 1 should be ignored.

A When the interrupt is asserted, it is taken regardless of the value of the PSTATE mask bit. The target Exception level might be using AArch64 or AArch32.

B When the interrupt is asserted, it is subject to the corresponding PSTATE mask bit. If the value of the mask is 1, the interrupt is not taken. If the value of the mask is 0, the interrupt is taken.
Taking an interrupt or other exception during a multiple-register load or store

In AArch32 state, an interrupt cannot be taken during a sequence of memory accesses caused by a single load or store instruction, except that when ARMv8.2-LSMAOC is implemented and the value of the applicable LSMAOE field is 0, an interrupt can be taken between two memory accesses made by a single AArch32 Load Multiple (LDM) or Store Multiple (STM) instruction.

The applicable LSMAOE field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the LDM or STM instruction is executed.

When the value of the LSMAOE bit is 0 and an interrupt is taken between two memory accesses made by a single AArch32 LDM or STM instruction, then:

- For a load, any register being loaded by the instruction other than a register used in the generation of the address by the instruction or the PC, can contain an UNKNOWN value. Any register used in the generation of the address is restored to its initial value and the LR is set on the interrupt to a value consistent with returning to the instruction.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

ARMv8.2 deprecates software relying on interrupts not being taken during the sequence of memory accesses caused by a single load or store instruction.
G1.16 AArch32 state exception descriptions

Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- **Undefined Instruction exception.**
- **Monitor Trap exception** on page G1-5276.
- **Hyp Trap exception** on page G1-5277.
- **Supervisor Call (SVC) exception** on page G1-5278.
- **Secure Monitor Call (SMC) exception** on page G1-5279.
- **Hypervisor Call (HVC) exception** on page G1-5280.
- **Prefetch Abort exception** on page G1-5281.
- **Data Abort exception** on page G1-5285.
- **Virtual SError interrupt exception** on page G1-5289.
- **IRQ exception** on page G1-5290.
- **Virtual IRQ exception** on page G1-5292.
- **FIQ exception** on page G1-5292.
- **Virtual FIQ exception** on page G1-5294.

Additional pseudocode functions for exception handling on page G1-5294 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

G1.16.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, HCPTR, and DBGDSCRext.
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
  - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See Floating-point exceptions and exception traps on page E1-3545.
  - Execution of certain floating-point instructions when one or both of the FPSCR.\{Stride, Len\} fields in nonzero, in an implementation in which those fields are RW. The description of FPEXC specifies the instructions to which this applies.
- An instruction that is **UNDEFINED**.

--- Note ---

The Undefined Instruction exception is taken using offset \(0x04\) in the Hyp, Secure, or Non-secure vector table. In the Monitor vector table this offset is used for the Monitor Trap exception. See Monitor Trap exception on page G1-5276 and The vector tables and exception offsets on page G1-5240.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Undefined Instruction exception is taken on page G1-5275.

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- Lazy context switching of System registers.
The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the SPSR and LR_und values generated by the exception entry, as follows:
  - If SPSR.T is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-5261.

--- **Note**
If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

### The PE mode to which the Undefined Instruction exception is taken

*Figure G1-4* shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken, when the exception is taken to an Exception level that is using AArch32.

**Figure G1-4** The PE mode an Undefined Instruction exception is taken to in AArch32 state

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-5252.
Pseudocode description of taking the Undefined Instruction exception

The AArch32.UndefinedFault() pseudocode procedure determines whether the Undefined Instruction exception is taken to AArch32 state. If it is taken to AArch32 state, the AArch32.TakeUndefInstrException() pseudocode procedure describes how the PE takes the exception.

An Undefined Instruction exception is taken to an Exception level using AArch64 if either:

- It is generated in User mode when EL1 is using AArch64.
- It is generated in User mode when EL2 is enabled in the current Security state and is using AArch64 and the value of HCR_EL2.TGE is 1.

Conditional execution of undefined instructions

The conditional execution rules described in Conditional execution on page F2-3655 apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception:
  - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.
  - The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

Note

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

Note

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.

G1.16.2 Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.
The Monitor Trap exception is taken using offset 0x04 in the Monitor vector table. In the other vector tables, this offset is used for the Undefined Instruction exception. See Undefined Instruction exception on page G1-5274 and The vector tables and exception offsets on page G1-5240.

A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a WFI or WFE instruction that would otherwise cause suspension of execution when:
• In the case of the WFI instruction, the value of the SCR.TWI bit is 1.
• In the case of the WFE instruction, the value of the SCR.TWE bit is 1.

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the SPSR and LR_mon values generated by the exception entry, as follows:
• If SPSR.T is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
• If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see Exception return to an Exception level using AArch32 on page G1-5261.

The PE mode to which the Monitor Trap exception is taken

When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of 0x04 from the Monitor exception base address.

Pseudocode description of taking the Monitor Trap exception

The AArch32.TakeMonitorTrapException() pseudocode procedure describes how the PE takes the exception.

Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor. The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32. A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the HCR, HCPTR, HDCR, or HSTR. For more information see EL2 configurable controls on page G1-5323.

Traps to Hyp mode never apply in Secure state, regardless of the value of the SCR.NS bit.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

The SPSR and ELR_hyp values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying ELR_hyp, and possibly updating SPSR_hyp.

When the PE enters the handler for a Hyp Trap exception, the HSR holds syndrome information for the exception. For more information see Use of the HSR on page G5-5572.
The PE mode to which the Hyp Trap exception is taken

A Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.

Pseudocode description of taking the Hyp Trap exception

The `AArch32.TakeHypTrapException()` pseudocode procedure describes how the PE takes the exception.

G1.16.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see SVC on page F5-4410.

Note

In an implementation that includes EL2, when EL2 is using AArch32:

1. When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see SVC on page F5-4410.
2. When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-5255.

By default, a Supervisor Call exception that is taken to AArch32 state is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Supervisor Call exception is taken.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. For an exception taken to AArch32 state, this return is performed as follows:

1. If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR_svc values generated by the exception entry, in an exception return instruction without subtraction.
2. If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-5261.

The PE mode to which the Supervisor Call exception is taken

Figure G1-5 on page G1-5279 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken, when the exception is taken to an Exception level that is using AArch32.
Figure G1-5 The PE mode the Supervisor Call exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-5252.

Pseudocode description of taking the Supervisor Call exception

The \texttt{AArch32.CallSupervisor()} pseudocode procedure determines whether the Supervisor Call exception is taken to AArch32 state. If it is taken to AArch32 state, the \texttt{AArch32.TakeSVCException()} pseudocode procedure describes how the PE takes the exception.

An Supervisor Call exception is taken to an Exception level using AArch64 if either:

- It is generated by executing an SVC instruction in User mode when EL1 is using AArch64.
- It is generated by executing an SVC instruction in Non-secure User mode when EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

G1.16.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see SMC on page F5-4257.

\textbf{Note}

- In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when HCR.TSC 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-5330.
• The Operation pseudocode in the description of the AArch32 SMC instruction, in SMC on page F5-4257, identifies cases where execution of the instruction generates an exception that is taken to EL3 using AArch64.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. For an exception taken to AArch32 state, this return is performed using the SPSR and LR_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see Exception return to an Exception level using AArch32 on page G1-5261.

Note

For an exception taken to AArch32 state, the exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then asynchronous exceptions might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

• The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.

• The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset 0x08 from the Monitor exception base address.

Note

• An SMC instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see The PE mode to which the Hyp Trap exception is taken on page G1-5278.

• If EL3 is using AArch64 then Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64 on page G1-5250 describes the effect of executing an SMC instruction at an Exception level that is using EL1.

Pseudocode description of taking the Secure Monitor Call exception

The AArch32.TakeSMCException() pseudocode procedure describes how the PE takes the exception when the exception is taken to an Exception level that is using AArch32.

G1.16.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see HVC on page F5-3939.

Note

• Execution of HVC instructions is disabled when the value of SCR.HCE is 0. Descriptions of HVC instruction execution elsewhere in this section assume the Effective value of SCR.HCE is 1.

• When EL2 is using AArch64 an HVC instruction executed in a Non-secure EL1 mode generates an exception that is taken to EL2 using AArch64. Exception classes and the ESR_ELx syndrome registers on page D1-2172 describes how this exception is reported in ESR_EL2.
The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-5261.

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information see Use of the HSR on page G5-5572.

The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

![Figure G1-6 The PE mode the Hypervisor Call exception is taken to in AArch32 state](image)

Pseudocode description of taking the Hypervisor Call exception

The AArch32.CallHypervisor() pseudocode procedure determines whether the valid execution of an HVC instruction in AArch32 state generates an exception that is taken to EL2 using AArch64, or generates a Hypervisor Call exception taken to Hyp mode. The AArch32.TakeHVCException() pseudocode procedure describes how the PE takes a Hypervisor Call exception.

G1.16.7 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

    Note

    Asynchronous External aborts on instruction fetches are reported as SError interrupts using the Data Abort exception, see Data Abort exception on page G1-5285.

    A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.
    For more information about memory aborts see VMSAv8-32 memory aborts on page G5-5546.

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see Chapter G2 AArch32 Self-hosted Debug.

    Note

    If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

    - Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.

    - Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.
By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Prefetch Abort exception is taken to an Exception level that is using AArch32, see The PE mode to which the Prefetch Abort exception is taken on page G1-5283.
- About cases where the Prefetch Abort generates an exception that is taken to an Exception level that is using AArch64, see Pseudocode description of taking the Prefetch Abort exception on page G1-5285.

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Prefetch Abort exceptions in AArch32 state see Exception return to an Exception level using AArch32 on page G1-5261.

Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

If the exception is taken to EL1 using AArch32 or EL3 using AArch32

- The IFSR indicates the cause of the exception:
  - If the value of TTBCR.EAE is 0, IFSR.FS takes the value 0b00001.
  - If the value of TTBCR.EAE is 1, IFSR.STATUS takes the value 0b100001.
- IFAR holds the value of the address that faulted, including the misaligned low order bit or bits.
- R14_abt holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

If the exception is taken to EL2 using AArch32

- HSR_EC takes the value 0b100010.
- HSR_IL is UNKNOWN.
- HSR_ISS is RES0.
- HIIFAR and ELR_hyp each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the CONSTRAINED UNPREDICTABLE behavior of a branch to an unaligned PC value, as described in Branching to an unaligned PC on page K1-7196, then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in Exiting Debug state on page H2-6452, then it is CONSTRAINED UNPREDICTABLE whether bit[0] of the faulting address is forced to zero.
The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 on page G1-5284 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken, when the exception is taken to an Exception level that is using AArch32.

——— Note ————
In this figure, the Effective value of HCR2.TEA is 0 if the RAS Extension is not implemented.
Figure G1-7 The PE mode the Prefetch Abort exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-5252.
Pseudocode description of taking the Prefetch Abort exception

The AArch32.Abort() pseudocode function determines whether the Prefetch Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Prefetch Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the AArch32.TakePrefetchAbortException() pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of HCR_EL2.TGE is 1 and the exception is generated in Non-secure User mode.
  - The value of MDCR_EL2.TDE is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of SCR_EL3.EA is 1. and the exception is generated by an External abort in AArch32 state.

G1.16.8 Data Abort exception

In AArch32 state, a Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError interrupt. The SError interrupt might be caused by an External abort on a memory access, which can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously.

As described in Asynchronous exception masking controls on page G1-5269, SError interrupts can be masked. When this happens, a generated SError interrupt is not taken until it is not masked.

- A watchpoint, see Watchpoint exceptions on page G2-5391.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Data Abort exception is taken to an Exception level that is using AArch32 see The PE mode to which the Data Abort exception is taken on page G1-5286.
- About memory aborts in AArch32 state see VMSAv8-32 memory aborts on page G5-5546.
- About cases where the Data Abort generates an exception that is taken to an Exception level that is using AArch64 see Pseudocode description of taking the Data Abort exception on page G1-5288.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError interrupt exception was taken. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Data Abort exceptions in AArch32 state see *Exception return to an Exception level using AArch32* on page G1-5261.

**The PE mode to which the Data Abort exception is taken**

Figure G1-8 on page G1-5287 shows the determination of the mode to which a Data Abort exception is taken when the exception is taken to an Exception level that is using AArch32.

--- **Note**

In this figure, the Effective value of HCR2.TEA is 0 if the RAS Extension is not implemented.
Figure G1-8 The PE mode the Data Abort exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-5252.
Pseudocode description of taking the Data Abort exception

The `AArch32.Abort()` pseudocode function determines whether the Data Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Data Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the `AArch32.TakeDataAbortException()` pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of HCR_EL2.TGE is 1 and the exception is generated in Non-secure User mode.
  - The value of MDCR_EL2.TDE is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of SCR_EL3.EA is 1. and the exception is generated by an External abort in AArch32 state.

Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - An Alignment fault is generated.
  - An MMU fault is generated.
  - A Watchpoint is generated.
  - An External abort is generated, if that External abort is taken synchronously.
- UNKNOWN for any location for which no exception and no debug event is generated.

If the access to a memory location generates an External abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the External abort. However, in general, ARM recommends that such locations are unchanged.

For External aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying base register writeback, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have constrained unpredictable results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct transfer to or from the Debug Communication Channel (DCC) register, using the LDC and STC instructions. For more information see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.
  - If the instruction that accesses the DCC registers is an LDC or STC instruction, UNKNOWN values are left in the Data Transfer Register and DCC flow-control flags.
- By modifying PSTATE.
If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- **On entry to the Data Abort exception handler:**
  - The PC value is the Data Abort vector address, see *Exception vectors and the exception base address* on page G1-5239.
  - The LR_abt value is determined from the address of the aborted instruction.

Neither value is affected by the results of any load specified by the instruction.

- **The base register is restored to its original value if either:**
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.

- If the instruction only loads one general-purpose register the value in that register is unchanged.

- If the instruction loads more than one general-purpose register, **UNKNOWN** values are left in destination registers other than the PC and the base register of the instruction.

- If the instruction affects any registers in the Advanced SIMD and floating-point register file, **UNKNOWN** values are left in the registers that are affected.

- **PSTATE bits** that are not defined as updated on exception entry retain their current value.

- **If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.**

After taking a Data Abort exception, the state of the Exclusives monitors is **UNKNOWN**. Therefore, ARM strongly recommends that the abort handler performs a **CLREX** instruction, or a dummy **STREX** instruction, to clear the Exclusives monitor state.

An External abort might signal a data corruption to the PE. For example a memory location might have been corrupted. The error that caused the External abort might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

### The ARM abort model

The abort model used by an ARM PE is described as a **Base Restored Abort Model**. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

#### G1.16.9 Virtual SError interrupt exception

The Virtual SError interrupt exception is implemented only as part of EL2 is enabled in the current Security state.

A Virtual SError interrupt exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of **PSTATE.A** is 0.
- Either:
  - EL2 is using AArch32 and the values of the **HCR, {TGE, AMO, VA}** bits are {0, 1, 1}.
  - EL2 is using AArch64 and the values of the **HCR_EL2, {TGE, AMO, VA}** bits are {0, 1, 1}.

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state, this return is performed using the **SPSR** and **LR_abt** values generated by the exception entry, using an exception return instruction without subtraction.
The PE mode to which the Virtual SError interrupt exception is taken

The Virtual SError interrupt exception is taken using a vector offset of 0x10 from the Non-secure exception base address.

The conditions for generating a Virtual SError interrupt exception in AArch32 state mean the exception is:

• Taken from a EL1 or EL0 mode.
• Taken to Abort mode if EL1 is using AArch32.
• Taken to EL1, when EL0 is using AArch32 and EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-5266.

Note

Because a Virtual SError interrupt exception taken to AArch32 state is always taken to Abort mode, on exception entry the preferred return address is always saved to LR_abt.

Pseudocode description of taking the Virtual SError interrupt exception

The AArch32.TakeVirtualSSErrorException() pseudocode procedure describes how the PE takes the exception.

G1.16.10   IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-5269, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

• EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
• EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

• About cases where the exception is taken to an Exception level using AArch32 see The PE mode to which the physical IRQ exception is taken on page G1-5291.
• About cases where the exception is taken to an Exception level using AArch64 see Pseudocode description of taking the physical IRQ exception on page G1-5291.

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

• If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  — SPSR_irq and LR_irq if returning from IRQ mode.
  — SPSR_mon and LR_mon if returning from Monitor mode.
• If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see Exception return to an Exception level using AArch32 on page G1-5261.
The PE mode to which the physical IRQ exception is taken

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken when the exception is taken to an Exception level that is using AArch32.

Pseudocode description of taking the physical IRQ exception

The AArch32.TakePhysicalIRQException() pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from User mode, EL2 is implemented in the current Security state and using AArch64, and the value of HCR_EL2.TGE is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from EL0 or EL1 mode, EL2 is implemented in the current Security state and using AArch64, and the value of HCR_EL2.IMO is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of SCR_EL3.IRQ is 1. The Exception is taken to EL3 using AArch64.
G1.16.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual IRQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of PSTATE.I is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.{TGE, IMO} is \{0, 1\}.
  - EL2 is using AArch64 and the value of HCR_EL2.{TGE, IMO} is \{0, 1\}.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VI is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VI is 1.
  - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception uses a vector offset of 0x18.

The conditions for generating a Virtual IRQ exception in AArch32 state mean the exception is:

- Taken from an EL1 or EL0 mode.
- Taken to IRQ mode if EL1 is using AArch32.
- Taken to EL1 if EL0 is using AArch32 and EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-5266.

Pseudocode description of taking the Virtual IRQ exception

The AArch32.TakeVirtualIRQException() pseudocode procedure describes how the PE takes the exception.

G1.16.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-5269, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the exception is taken to an Exception level using AArch32 see The PE mode to which the physical FIQ exception is taken on page G1-5293.
- About cases where the exception is taken to an Exception level using AArch64 see Pseudocode description of taking the FIQ exception on page G1-5294.
The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_fiq and LR_fiq if returning from FIQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information see *Exception return to an Exception level using AArch32* on page G1-5261.

**The PE mode to which the physical FIQ exception is taken**

Figure G1-9 on page G1-5291 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken when the exception is taken to an Exception level that is using AArch32.

![Figure G1-10 The PE mode the FIQ exception is taken to in AArch32 state](image-url)
Pseudocode description of taking the FIQ exception

The `AArch32.TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from User mode, EL2 is implemented in the current Security state and using AArch64, and the value of HCR_EL2.TGE is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from an EL0 or EL1 mode, EL2 is implemented in the current Security state and using AArch64, and the value of HCR_EL2.FMO is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of SCR_EL3.FIQ is 1. The Exception is taken to EL3 using AArch64.

G1.16.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual FIQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of PSTATE.F is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.\{TGE, FMO\} is \{0, 1\}.
  - EL2 is using AArch64 and the value of HCR_EL2.\{TGE, FMO\} is \{0, 1\}.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VF is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VF is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is taken using a vector offset of 0x1C.

The conditions for generating a Virtual FIQ exception in AArch32 state mean the exception is:

- Taken from EL1 or EL0.
- Taken to FIQ mode if EL1 is using AArch32.
- Taken to EL1 if EL0 is using AArch32 and EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-5266.

Pseudocode description of taking the Virtual FIQ exception

The `AArch32.TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception.

G1.16.14 Additional pseudocode functions for exception handling

The `AArch32.EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes.
The `AArch32.EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The `AArch32.EnterMode()` pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The `AArch32.EnterMonitorMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMode()` functions are described in Chapter J1 *ARMv8 Pseudocode*. 
G1 The AArch32 System Level Programmers’ Model
G1.17 Reset into AArch32 state

G1.17 Reset into AArch32 state

Reset on page D1-2166 describes the ARMv8 reset model, including the defined levels of reset. When reset is deasserted, the PE starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

Note

- This section describes the architectural requirements for a reset into AArch32 state. It takes no account of whether ARM licenses any particular combination of Exception levels and Execution state. For more information about the licensed combinations, see Support for Exception levels and Execution states on page D1-2277.
- The Execution state in which the highest implemented Execution level starts executing instructions on coming out of reset might be determined by a configuration input signal.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in PE state on reset into AArch32 state on page G1-5297. For more information about behavior when resetting into an Exception level using AArch32, see:

- Behavior of caches at reset on page G4-5431.
- Enabling stages of address translation on page G5-5466.
- TLB behavior at reset on page G5-5526.
- Reset and debug on page H6-6529.

When reset is deasserted, if the PE resets into an Exception level that is using AArch32, it is IMPLEMENTATION DEFINED whether execution starts:

- From an IMPLEMENTATION DEFINED address.
- If reset is into EL3 or EL1, from the low or high reset vector address, as determined by the reset value of the SCTLR.V bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

Note

This option might be implemented for compatibility with earlier versions of the architecture.

Software might be able to identify the reset address:

- If reset is into EL3, by reading the reset value of MVBAR. That is, after coming out of reset, by reading MVBAR before the boot software has updated it. It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported.
- If reset is into EL2 or EL1, by reading RVBAR. RVBAR can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3.

If RVBAR is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for RVBAR is UNDEFINED.

The ARM architecture does not define any way of returning to a previous Execution state from a reset.
G1.17.1 PE state on reset into AArch32 state

--- Note ---
See the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0, and version 4.0 for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch32 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- The global exclusive monitor and local exclusive monitor for the PE are UNKNOWN.
- If reset is into EL3 using AArch32, then all fields of the SCR reset to zero.

--- Note ---
This means SCR.NS correctly indicates that the PE is in Secure state.

- If reset is into EL2 using AArch32, then reset is into Hyp mode and CPSR.M resets to 0b1010, otherwise reset is into Supervisor mode and CPSR.M resets to 0b0011,
- CPSR.IL resets to 0.
- The CPACR.{cp11, cp10} fields reset to zero, and if CPACR.ASEDIS is implemented as an RW field it resets to zero.

--- Note ---
When CPACR.TRCDIS is an RW field, its reset value is architecturally UNKNOWN.

- PSTATE is reset to the values defined by the AArch32.TakeReset() pseudocode function, see Pseudocode descriptions of reset on page G1-5299.
- The FPEXC.EN field resets to 0.
- In the SCTLR:
  - The {AFE, TRE, UWXN, WXN, I, SED, ITD, C, A, M} fields reset to 0.
  - The {nTWE, nTWI, CP15BEN} fields reset to 1.
  - The {TE, EE, V} fields reset to IMPLEMENTATION DEFINED values, see the register description for more information.

When the reset is to EL3 using AArch32 then these reset values apply only to the Secure instance of the SCTLR, and the reset value of the Non-secure SCTLR is architecturally UNKNOWN.

- All field of the TTBCR reset to 0.
  When the reset is to EL3 using AArch32 then:
  - All fields of the Secure TTBCR reset to 0.
  - In the Non-secure TTBCR, the EAE field resets to 0, and the reset values of all other fields are architecturally UNKNOWN.

- The VBAR resets to an IMPLEMENTATION DEFINED value.
  When the reset is to EL3 using AArch32 then this reset value applies only to the Secure instance of the register, and the reset value of the Non-secure VBAR is architecturally UNKNOWN.

- All fields of the DBGDCCINT reset to 0.
- The DBGDSCRext.{MDBGen, UDCCdis} fields reset to 0.
- The DBGOSDLR.DLK field resets to 0.
In addition:

**If the reset is into EL1 using AArch32**

- In the **RMR** register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a Cold reset.

**If the reset is into EL2 using AArch32**

- In the **HRMR**, the RR field resets to 0 on any warm or Cold reset, and the AA64 field resets to 0 on a Cold reset.
- The **HSCTLR**. {I, C, M} fields all reset to 0, and the **HSCTLR**.EE field resets to an IMPLEMENTATION DEFINED value.

**If the reset is into EL2 using AArch32 or into EL3 using AArch32**

For a reset into EL3 using AArch32 these reset values apply only if the implementation includes EL2, see the register descriptions for more information.

- All fields of the **HCPTR** reset to zero.
- All fields of the **HCR** reset to zero.
- The **HCR2**. {ID, CD} fields reset to zero.
- All fields of the **HSTR** reset to zero.
- The **VMPIDR** resets to the value of the **MPIDR**, see the register description for more information.
- The **VPIDR** resets to the value of the **MIDR**, see the register description for more information.
- The **VTTBR**. VMID field resets to zero.
- In the **HDCR**:
  - The HPMN field resets to the IMPLEMENTATION DEFINED value of **PMCR**.N.
  - The reset value of the HPME field is architecturally UNKNOWN.
  - All other fields reset to 0.

**If the reset is into EL3 using AArch32**

- The **MVBAR** resets to an IMPLEMENTATION DEFINED value, see the register description for more information.
- If the **NSACR**. {NSTRCDIS, NSASEDIS} fields are RW fields then they reset to 0.

**For either a warm or a Cold reset**

- The **EDPRSR**.SR field resets to 1.
- The **EDESR**. {SS, RC, OSUC} fields reset to 0.

**For a Cold reset only**

- The **EDSCR**. {RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} fields reset to 0.
- The **EDECCR**. {NSE, SE} fields reset to 0.
- The **EDPRSR**. {SPMAD, SDAD} fields reset to 0, and the **EDPRSR**. SPD field resets to 1.
- The **DBGOSLSR**. OSLK field resets to 1.
- The **DBGPRCR**. CORENPDPRQ field resets to the value of **EDPRCR**. COREPURQ.
An External Debug reset sets EDPRCR.COREPURQ to 0, see External debug register resets on page H8-6556. If an External Debug reset and a Cold reset coincide, both DBGPRCR.CORENPRDRQ and EDPRCR.COREPURQ are reset to 0.

- The debug CLAIM bits are reset to 0.

**Note**
These are the bits that are set to 1 by writing to DBGCLAIMSET.CLAIM, and reset to 0 by writing to DBGCLAIMCLR.CLAIM.

- Each bit of AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, and AMCNTENSET1 is set to 0.
- Each of the implemented architected activity monitor counters AMEVCNTR0<n> and each of the implemented auxiliary activity monitor counters AMEVCNTR1<n> are set to 0.

For more information about resets in AArch32 System registers, see Chapter G8 AArch32 System Register Descriptions.

**G1.17.2 Pseudocode descriptions of reset**

The AArch32.TakeReset() pseudocode procedure describes how the PE behaves when reset is deasserted.

The AArch32.ResetGeneralRegisters() pseudocode function resets the general-purpose registers.

The AArch32.ResetSIMDFPRegisters() pseudocode function resets the SIMD and floating-point registers.

The AArch32.ResetSpecialRegisters() pseudocode function resets the Special-purpose registers, and the debug System registers DLR and DSPSR, that are used for handling Debug exceptions.

The AArch32.ResetSystemRegisters() pseudocode function resets all System registers in the (coproc==0b111x) encoding space to their reset state as defined in the register descriptions in Chapter G8 AArch32 System Register Descriptions.

**Note**
The ResetSystemRegisters() function only resets the System registers. It has no effect on memory-mapped registers.

The ResetExternalDebugRegisters() pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 External Debug Register Descriptions.
The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- Wait For Event and Send Event.
- Wait For Interrupt on page G1-5303.

### G1.18.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. Example G1-2 describes how a spinlock implementation might use this mechanism to save energy.

**Example G1-2 Spinlock as an example of using Wait For Event and Send Event**

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page E2-3599.
- If the PE obtains the lock, it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point, it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system, the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation, the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a WFE instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
  - The Event Register is not set.
  - There is not a pending WFE wakeup event.

For more information about the trap to EL2, see Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-5333.

The architecture does not define the exact nature of the low power state entered as a result of executing a WFE instruction, but the execution of a WFE instruction must not cause a loss of memory coherency.
--- Note ---

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

---

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see WFE wake-up events on page G1-5302.
- The Event Register, see The Event Register.
- The Send Event instructions, see The Send Event instructions on page G1-5302.
- The Wait For Event instruction, see The Wait For Event instruction.

**The Event Register**

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a **WFE** instruction.

The reset value of the Event Register is **UNKNOWN**.

The Event Register for a PE is set by:

- The execution of an **SEV** instruction on any PE in the multiprocessor system.
- The execution of an **SEVL** instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see Event streams on page G6-5599.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

**The Wait For Event instruction**

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the **WFE** instruction completes.

The execution in AArch32 state of a **WFE** instruction that would otherwise cause suspension of execution might be trapped, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-5317.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-5333.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-5344.
The Wait For Event instruction, \texttt{WFE}, is available at all privilege levels, see \textit{WFE} on page F5-4508.

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.

\textbf{WFE wake-up events}

The following events are \textit{WFE} wake-up events:

\begin{itemize}
  \item The execution of an \texttt{SEV} instruction on any PE in the system.
  \item The execution of an \texttt{SEVL} instruction on the PE.
  \item A physical IRQ interrupt, unless masked by the \texttt{PSTATE.I} bit.
  \item A physical FIQ interrupt, unless masked by the \texttt{PSTATE.F} bit.
  \item A physical SError interrupt, unless masked by the \texttt{PSTATE.A} bit.
  \item In Non-secure state in any mode other than Hyp mode:
    \begin{itemize}
      \item When \texttt{HCR.IMO} is set to 1, a virtual IRQ interrupt, unless masked by the \texttt{PSTATE.I} bit.
      \item When \texttt{HCR.FMO} is set to 1, a virtual FIQ interrupt, unless masked by the \texttt{PSTATE.F} bit.
      \item When \texttt{HCR.AMO} is set to 1, a virtual SError interrupt, unless masked by the \texttt{PSTATE.A} bit.
    \end{itemize}
  \item An asynchronous External Debug Request debug event, if halting is allowed. For the definition of \textit{halting is allowed}, see \textit{Halting allowed and halting prohibited} on page H2-6417. \textit{See also External Debug Request debug event on page H3-6473.}
  \item An event sent by the timer event stream, see \textit{Event streams} on page D10-2651.
  \item An event sent by some \texttt{IMPLEMENTATION DEFINED} mechanism.
  \item An event caused by the clearing of the global monitor associated with the PE.
\end{itemize}

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and \texttt{EDSCR.HDE} is set to 1, \texttt{EDSCR.INTdis} can mask interrupts, including masking them acting as WFE wake-up events. See the register description for more information.

As shown in the list of wake-up events, an implementation can include \texttt{IMPLEMENTATION DEFINED} hardware mechanisms to generate wake-up events.

--- Note ---

For more information about \texttt{PSTATE} masking, see \textit{Asynchronous exception masking controls} on page G1-5269. If the configuration of the masking controls provided by EL2 and EL3 mean that a \texttt{PSTATE} mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the \texttt{PSTATE} mask bit.

--- The Send Event instructions ---

The Send Event instructions are:

\textbf{SEV, Send Event} This causes an event to be signaled to all PEs in the multiprocessor system.

\textbf{SEVL, Send Event Local} This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is \texttt{IMPLEMENTATION DEFINED}. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the \texttt{SEV} instruction. Therefore, ARM recommends that software includes a \texttt{DSB} instruction before any \texttt{SEV} instruction.

--- Note ---

A \texttt{DSB} instruction ensures that no instruction, including any \texttt{SEV} instruction, that appears in program order after the \texttt{DSB} instruction, can execute until the \texttt{DSB} instruction has completed. For more information, see \textit{Data Synchronization Barrier (DSB)} on page E2-3570.
The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

**Pseudocode description of the Wait For Event mechanism**

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `IsEventRegisterSet()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

**G1.18.2 Wait For Interrupt**

AArch32 state supports Wait For Interrupt through an instruction, WFI, that is provided in the A32 and T32 instruction sets. For more information, see *WFI* on page F5-4510.

When a PE issues a WFI instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a WFI instruction that would otherwise cause suspension of execution might be trapped, see:

- *Traps to Undefined mode of EL0 execution of WFE and WFI instructions* on page G1-5317.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-5333.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-5344.

The execution of a WFI instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

**WFI wake-up events**

The PE can remain suspended in its WFI state until it is reset, or one of the following WFI wake-up events occurs:

- A physical IRQ interrupt, regardless of the value of the PSTATE.I bit.
- A physical FIQ interrupt, regardless of the value of the PSTATE.F bit.
- A physical SError interrupt, regardless of the value of the PSTATE.A bit.
- In Non-secure state in any mode other than Hyp mode:
  - When HCR.IMO is set to 1, a virtual IRQ interrupt, regardless of the value of the PSTATE.I bit.
  - When HCR.FMO is set to 1, a virtual FIQ interrupt, regardless of the value of the PSTATE.F bit.
  - When HCR.AMO is set to 1, a virtual SError interrupt, regardless of the value of the PSTATE.A bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-6417.
  
  See also *External Debug Request debug event* on page H3-6473.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the WFI instruction completes.

WFI wake-up events cannot be masked by the mask bits in the PSTATE.
The architecture does not define the exact nature of the low power state, but the execution of a WFI instruction must not cause a loss of memory coherency.

--- Note ---

- Because debug events are WFI wake-up events, ARM strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

---

Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a WFI instruction. Typically, the WFI instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2.Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If the OS Double Lock is implemented and the value of DBGOSDLR.DLK, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

--- Note ---

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains, see Power domains and debug on page H6-6519.

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode description of Wait For Interrupt

The WaitForInterrupt() pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
G1.19 The AArch32 System register interface

In ARMv8, most System registers are accessed using the instructions described in System register access instructions on page F1-3633. The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters \{coproc, opc1, CRn, CRm, opc2\}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions.
- To maintain compatibility with previous versions of the ARM architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

Note
See Background to the System register interface on page G1-5306 for more information.

The following sections give more information about the AArch32 System register interface:

- System registers in the coproc == 0b111x encoding space.
- Access to System registers.
- Access controls for Advanced SIMD and floating-point functionality.
- Pseudocode description of checking accesses to the System registers on page G1-5306.
- Background to the System register interface on page G1-5306.

G1.19.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
  - Debug features, see Debug registers on page G8-6130.
  - Trace features, see the Embedded Trace Macrocell Architecture Specification.
  - Identification registers for the Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-5237.
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information, see Chapter G8 AArch32 System Register Descriptions.

G1.19.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0 the register descriptions in Chapter G8 AArch32 System Register Descriptions indicate whether a register is accessible from EL0.

G1.19.3 Access controls for Advanced SIMD and floating-point functionality

In ARMv8, the CPACR controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The \{cp10, cp11\} fields control access to all Advanced SIMD and floating-point functionality, and can:
  - Disable EL0 and PL1 access to this functionality.
  - Enable access to this functionality at PL1 only.
  - Enable access to this functionality at EL0 and PL1.
- The ASEDIS field controls access to Advanced SIMD instructions that are not also floating-point instructions.
Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

--- Note ---
The CPACR has no effect on accesses from Hyp mode.

If an implementation includes EL3, the NSACR determines whether Advanced SIMD and floating-point functionality can be accessed from Non-secure state:

- The \{cp10, cp11\} fields control Non-secure access to all Advanced SIMD and floating-point functionality.
- The NSASEDIS field controls Non-secure access to Advanced SIMD instructions that are not also floating-point instructions.

If an implementation includes EL2, the HCPTR provides additional controls on Non-secure accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the CPACR and NSACR settings, setting HCPTR bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the HCPTR:

- The \{TCP10, TCP11\} fields control access to all Advanced SIMD and floating-point functionality.
- The TASE field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The TCPAC field traps Non-secure EL1 accesses to the CPACR to Hyp mode.

For more information, see General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-5334.

--- Note ---
Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. In ARMv8, if these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE, see Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-7200.

For more information about Advanced SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-5308.

G1.19.4 Pseudocode description of checking accesses to the System registers

The AArch32.CheckSystemAccess() function determines whether a System register access instruction that targets a System register in the (coproc == 0b111x) encoding space is accepted.

G1.19.5 Background to the System register interface

--- Note ---
This section is not part of the ARMv8 Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic coprocessor interface, that gave access to 15 coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by ARM, while CP0 - CP7 were available for IMPLEMENTATION DEFINED coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see System register access instructions on page F1-3633.
In the ARM coprocessor model, a coprocessor included both:

- Primary and secondary coprocessor registers, that form part of the coprocessor interface.
- A number of internal registers.

When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the coproc parameter and taking a value between p0 for CP0 and p15 for CP15.
- The primary coprocessor register, specified by the CRn parameter and taking a value between c0 and c15.
- The secondary coprocessor register, specified by the CRm parameter and taking a value between c0 and c15.
- Up to two additional parameters, opc1 and opc2, taking values between 0 and 7.

Other instructions in the group described in System register access instructions on page F1-3633 take a subset of these parameters:

- In the ARMv7 definitions, LDC and STC instructions take parameters \{coproc, CRd\}, where CRd is the primary coprocessor register.
- MCRR and MRRC instructions take parameters \{coproc, opc1, CRm\}, where CRm is the primary coprocessor register.

To maintain backwards compatibility, the arguments to an MCR or MRC instruction remain \{coproc, opc1, CRn, CRm, opc2\}. Correspondingly, the encoding of the AArch64 System registers is described using the parameters \{op0, op1, CRn, CRm, op2\}. However:

- The naming of these parameters no longer has any particular significance.
- While the coproc field is a 4-bit field, op0 is a 2-bit field.

Of the coprocessors reserved for use by ARM, in ARMv7 and earlier versions of the architecture:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. In ARMv8, these registers are described as being in the coproc == 0b1111 encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. In ARMv8, these registers are described as being in the coproc == 0b1110 encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
  - Generally ARMv8 does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
  - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.\{cp10, cp11\}. In these cases, both fields must be set to the same value. For more information, see Access controls for Advanced SIMD and floating-point functionality on page G1-5305.

In ARMv8:

- The AArch32 System registers include registers that were described as Special registers in ARMv7 and earlier versions of the architecture. This means that the ARMv8 System registers include registers that are outside the earlier coprocessor model.
- The ARMv7 AArch32 instruction encodings for LDC, STC, MCR, MCRR, and MRRC instructions with coproc field values other than \{1010, 1011, 1110, 1111\} are available for reuse. ARMv8.2 re-uses some encodings in this way.
G1.20 Advanced SIMD and floating-point support

Advanced SIMD and floating-point instructions on page E1-3542 introduces:
- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, that can be viewed as:
  - Singleword registers S0 - S31.
  - Doubleword registers D0 - D31.
  - Quadword registers Q0 - Q15.
- The Floating-Point Status and Control Register (FPSCR).

For more information about the System registers for the Advanced SIMD and floating-point operation, see Advanced SIMD and floating-point System registers on page G1-5310. Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

AArch32 implications of not including support for Advanced SIMD and floating-point summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:
- Enabling Advanced SIMD and floating-point support.
- Advanced SIMD and floating-point System registers on page G1-5310.
- Context switching when using Advanced SIMD and floating-point functionality on page G1-5311.
- Floating-point exceptions and exception traps on page G1-5312.

G1.20.1 AArch32 implications of not including support for Advanced SIMD and floating-point

As stated in Implementations not including Advanced SIMD and floating-point instructions on page D1-2277, although ARMv8-A generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets, for implementations targeting specialized markets, ARM might produce or license ARMv8-A implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:
- The CPACR.{ASEDIS, cp11, cp10} fields are RES0.
- The NSACR.{NSASEDIS, cp11, cp10} fields are RES0.
- The HCPTR.{TASE, TCP11, TCP10} fields are RES1.
- The FPEXC, FPSCR, FPSID, MVFR0, MVFR1, and MVFR2 registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.

G1.20.2 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in Configurable instruction enables and disables, and trap controls on page G1-5314, and this section:
- Summarizes those controls.
- Provides additional information in the following subsections:
  - FPEXC control of access to Advanced SIMD and floating-point functionality on page G1-5310.
  - EL0 access to Advanced SIMD and floating-point functionality on page G1-5310.
Note
This section shows the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to Advanced SIMD and floating-point functionality are:

**General \{cp10, cp11\} or \{TCP10, TCP11\} controls**
This relates to the CPACR.{cp10, cp11}, NSACR.{cp10, cp11}, and HCPTR.{TCP10, TCP11} controls.

Note
Background to the System register interface on page G1-5306 explains the naming of these controls.

The \{cp10, cp11\} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- **CPACR.{cp10, cp11}** control access from PE modes other than Hyp mode. These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- In an implementation that includes EL3, NSACR.{cp10, cp11} control access from Non-secure state.
- In an implementation that includes EL2, if NSACR.{cp10, cp11} permit Non-secure accesses, or if EL3 is not implemented, HCPTR.{TCP10, TCP11} provide an additional control on those accesses.

In each case, the \{cp10, cp11\} controls must be programmed to the same value, otherwise operation is CONSTRAINED UNPREDICTABLE. The ARMv8 CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information, see Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-7200.

For more information about these controls, see:
- Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-5319.
- General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-5334.
- Enabling Non-secure access to SIMD and floating-point functionality on page G1-5346.

**Control of accesses to the CPACR from Non-secure PL1 modes**
As stated in General \{cp10, cp11\} or \{TCP10, TCP11\} controls, the CPACR controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the CPACR from Non-secure PL1 modes can be trapped to EL2, see Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-5335.

**Additional controls of Advanced SIMD functionality**
- If implemented as an RW field, CPACR.ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.
- In an implementation that includes EL3, when CPACR.ASEDIS permits use of the Advanced SIMD instructions or if the CPACR.ASEDIS control is not implemented, NSACR.NSASEDIS can make all Advanced SIMD instructions UNDEFINED in Non-secure state.
- In an implementation that includes EL2, when the CPACR and NSACR settings permit Non-secure use of the Advanced SIMD instructions, if HCPTR.TASE is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a Non-secure PL0 or PL1 mode.
For more information about these controls, see:

- [Disabling PL0 and PL1 execution of Advanced SIMD instructions](#) on page G1-5320.
- [Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality](#) on page G1-5335.
- [Disabling Non-secure access to Advanced SIMD functionality](#) on page G1-5347.

*Pseudocode description of enabling SIMD and floating-point functionality* on page G1-5347 provides links to the pseudocode descriptions of all of these controls.

**FPEXC control of access to Advanced SIMD and floating-point functionality**

In addition, FPEXC.EN is an enable bit for most Advanced SIMD and floating-point operations. When FPEXC.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the FPEXC or FPSID register.
- A VMRS from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register.

These instructions can be executed only at EL1 or higher.

---

**Note**

- When the FPSID is accessible, any write access to the FPSID is ignored.
- When FPEXC.EN is 0, these operations are treated as UNDEFINED:
  - A VMSR to the FPSCR.
  - A VMRS from the FPSCR.

---

See [Enabling access to the SIMD and floating-point registers](#) on page G1-5320 for more information about the scope of the FPEXC.EN control.

When executing at EL0, the PE behaves as if the value of FPEXC.EN is 1 if either:

- EL1 is using AArch64.
- EL2 is enabled in the current Security state and is using AArch64, and the value of HCR_EL2.TGE is 1.

---

**Note**

In Non-secure state, if the value of HCR_EL2.RW is 0 then it is permitted for the value of FPEXC32_EL2.EN to control whether Advanced SIMD and floating-point functionality is enabled. However, ARM deprecates using the value of FPEXC32_EL2.EN to determine behavior.

---

**EL0 access to Advanced SIMD and floating-point functionality**

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the FPSCR.
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in *Advanced SIMD and floating-point System registers* on page E1-3544.

**G1.20.3 Advanced SIMD and floating-point System registers**

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- [Register map of the Advanced SIMD and floating-point System registers](#) on page G1-5311.
- [Accessing the Advanced SIMD and floating-point System registers](#) on page G1-5311.
Register map of the Advanced SIMD and floating-point System registers

Table G1-21 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide.

<table>
<thead>
<tr>
<th>Name</th>
<th>Permitted access</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPEXC</td>
<td>RW</td>
</tr>
<tr>
<td>FPSCR</td>
<td>RW</td>
</tr>
<tr>
<td>FPSID</td>
<td>RW(^a)</td>
</tr>
<tr>
<td>MVFR0</td>
<td>RO</td>
</tr>
<tr>
<td>MVFR1</td>
<td>RO</td>
</tr>
<tr>
<td>MVFR2</td>
<td>RO</td>
</tr>
</tbody>
</table>

\(^a\) When FPSID is accessible, VMSR accesses to FPSID are ignored.

In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see *Common System registers* on page G5-5589.

Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- VMRS on page F6-4894.
- VMSR on page F6-4897.

For example:

VMRS <Rt>, FPSID ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1 ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt> ; Write Floating-Point System Control Register

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see *Enabling Advanced SIMD and floating-point support* on page G1-5308.

---

**Note**

All hardware ID information can be accessed only from EL1 or higher. This means:

**The FPSID is accessible only from EL1 or higher.**

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

**The MVFR registers are accessible only from EL1 or higher.**

Unprivileged software must issue a system call to determine what features are supported.

---

G1.20.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software uses the CPACR, {cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see *Enabling Advanced SIMD and floating-point support* on page G1-5308. Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception.
operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

**G1.20.5 Floating-point exceptions and exception traps**

Execution of a floating-point instruction can generate an exceptional condition, called a floating-point exception.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

--- Note ---

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in AArch32 state exception descriptions on page G1-5274.

---

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the floating-point exceptions.
- For an implementation that does provide this capability, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} are RAZ/WI.

--- Note ---

- An Input Denormal floating-point exception is generated when a single-precision or double-precision floating-point value is flushed-to-zero because the value of FPSCR.FZ is 1. However, no Input Denormal exception is generated when a half-precision floating-point value is flushed-to-zero because the value of FPSCR.FZ16 is 1.
- The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

---

Trapped exception handling never causes the corresponding cumulative exception bit of the FPSCR to be set to 1. If this behavior is desired, the trap handler routine must use a read, modify, write sequence on the FPSCR to set the cumulative exception bit.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, except for the following cases when they are taken from EL0 to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

If the exception is taken to an Exception level that is using AArch64, then it is reported in the ELR_ELx for the Exception level to which it is taken, as described in Exception entry on page D1-2170.
If the exception is taken to an Exception level that is using AArch32, then it is taken as an Undefined Instruction exception, see *Undefined Instruction exception* on page G1-5274. The FPEXC identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

See also *Floating-point exceptions and exception traps* on page E1-3545.

In an implementation that provides synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch32 state.
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.

ARMv8 does not support the trapping of floating-point exceptions from Advanced SIMD instructions executed in AArch32 state.

The `AArch32.FPTrappedException()` and `FPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch32 state.

The `AArch32.FPTrappedException()` and `FPProcessException()` functions are described in Chapter J1 *ARMv8 Pseudocode.*
G1.21 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch32 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

The exception generated by attempting to execute an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.
  
  When the exception is taken to EL1, it is taken to Undefined mode.

- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
  - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
  - Otherwise, the exception is taken to Undefined mode.

Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are trapped.

Note

AArch32 trap controls are described in terms of Privilege levels, rather than Exception levels, because the PL1 traps apply at and are controlled from:

- EL1 In Non-secure state, and in Secure state when EL3 is using AArch64.
- EL3 In Secure state when EL3 is using AArch32.

For more information see Security state, Exception levels, and AArch32 execution privilege on page G1-5218.

Trap controls are grouped as:

PL1, excluding Monitor mode

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

For more information about these traps, see PL1 configurable controls on page G1-5315.

Hyp mode (PL2)

These traps apply only to execution in Non-secure state. This section only describes the traps that apply when EL2 is using AArch32.

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps, see EL2 configurable controls on page G1-5323.

See also Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

Monitor mode (Secure PL1)

This section only describes the traps that apply when EL3 is using AArch32.

Trapped instructions generate Monitor Trap exceptions, that are taken to Monitor mode.

For more information about these traps, see EL3 configurable controls on page G1-5342.
An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. Exception prioritization for exceptions taken to AArch32 state on page G1-5242 defines the prioritization of different exceptions on the same instruction.

Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the HSR.

--- Note ---

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, CPACR.TRCDIS is a trap control even though TRCDIS is a mnemonic for Trace Disable.

- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

- Configurable instruction enables and disables, and trap controls on page D1-2208 describes controls provided by AArch64 state for enabling, disabling, and trapping instructions. Generally, where an AArch64 control applies to execution at lower Exception levels, it traps the equivalent functionality when that lower Exception level is using AArch32. See the AArch64 trap controls for more information.

This section is organized as follows:

- Register access instructions.
- PL1 configurable controls.
- EL2 configurable controls on page G1-5323.
- EL3 configurable controls on page G1-5342.
- Pseudocode description of configurable instruction enables, disables, and traps on page G1-5347.

G1.21.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

G1.21.2 PL1 configurable controls

In AArch32 state, each control is associated with a particular System register field that is accessible:

- When EL3 is using AArch64, or when an implementation does not include EL3, from EL1.
- When EL3 is using AArch32:
  - In Non-secure state, from EL1.
  - In Secure state, from EL3.

This means that the controls are described as PL1 controls, because PL1 is defined as being the Privilege level of software that is executing:

- At EL3, if the PE is executing in EL3 and EL3 is using AArch32.
- At EL1 under all other conditions.

Where there is an AArch64 control that is equivalent to an AArch32 PL1 control, the AArch64 control is an EL1 control.

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

--- Note ---

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.
Table G1-22 shows the AArch32 System registers that contain these controls.

### Table G1-22 System registers that contain instruction enables and disables, and trap controls

</tbody>
</table>
When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-5254.

**Instructions that fail their Condition code check**

See *Conditional execution of undefined instructions* on page G1-5276.

**Trapping to PL1 of instructions that are UNPREDICTABLE**

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates an Undefined Instruction exception.

**Traps to Undefined mode of EL0 execution of \( \text{WFE} \) and \( \text{WFI} \) instructions**

\[ \text{SCTLR.} \{ \text{nTWE}, \text{nTWI} \} \] trap EL0 execution of \( \text{WFE} \) and \( \text{WFI} \) instructions to Undefined mode:

**SCTLR.nTWE**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>This control has no effect on the EL0 execution of ( \text{WFE} ) instructions.</td>
</tr>
<tr>
<td>0</td>
<td>Any attempt to execute a ( \text{WFE} ) instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.</td>
</tr>
</tbody>
</table>

**SCTLR.nTWI**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>This control has no effect on the EL0 execution of ( \text{WFI} ) instructions.</td>
</tr>
<tr>
<td>0</td>
<td>Any attempt to execute a ( \text{WFI} ) instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.</td>
</tr>
</tbody>
</table>

The attempted execution of a conditional \( \text{WFE} \) or \( \text{WFI} \) instruction is only trapped if the instruction passes its Condition code check.

---

**Note**

Since a \( \text{WFE} \) or \( \text{WFI} \) can complete at any time, even without a Wakeup event, the traps on \( \text{WFE} \) of \( \text{WFI} \) are not guaranteed to be taken, even if the \( \text{WFE} \) or \( \text{WFI} \) is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-5254.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait For Event and Send Event* on page G1-5300.
- *Wait For Interrupt* on page G1-5303.

**Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality**

Table G1-25 on page G1-5318 shows the deprecated AArch32 functionality that might have disable controls in the SCTLR:

- The SED control is always implemented.
- Whether each of the ITD or CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented, then the associated functionality cannot be disabled.

When an instruction is disabled by one of these controls, it is UNDEFINED at PL0 and PL1. This means an attempt to execute the instruction at PL0 or PL1 generates an Undefined Instruction exception that is taken to Undefined mode, unless both of the following apply, in which case the attempted execution generates an exception that is taken to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-5254:

- The instruction is executed at Non-secure EL0 using AArch32.
• Either:
  — EL2 is using AArch32 and the value of HCR.TGE is 1.
  — EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

Note
The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers

If implemented, the CPACR.TRCDIS control traps PL0 and PL1 System register accesses to the trace registers to Undefined mode, as follows:
1
  PL0 and PL1 accesses to the System register interface to the PE Trace Unit are trapped to Undefined mode
0
  This control has no effect on PL0 and PL1 accesses to the System register interface to the PE Trace Unit.

If the CPACR.TRCDIS control is not implemented, then the CPACR.TRCDIS field is RAZ/WI. This means the CPACR does not provide a trap to Undefined mode of PL1 and PL0 System register accesses to trace registers. See the register description for more information.

Note
• System register accesses to the PE Trace Unit use the (coproc==0b1111) encoding space.
• The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace System registers are UNDEFINED.
• The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace System registers can have side effects. When a System register access is trapped, no side effects occur before the exception is taken, see Register access instructions on page G1-5315.

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, CPACR.TRCDIS behaves as RAO/WI in Non-secure state. This behavior also applies if the CPACR.TRCDIS control is not implemented.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

Table G1-25 PL1 controls for disabling and enabling PL0 and PL1 use of AArch32 deprecated functionality

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the SCTLR&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Disabled instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED&lt;sup&gt;b&lt;/sup&gt;</td>
<td>SETEND instructions</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD&lt;sup&gt;c&lt;/sup&gt;</td>
<td>See the SCTLR.ITD description</td>
</tr>
<tr>
<td>Accesses to the CP15DMB, CP15DSB, and CP15ISB barrier instructions</td>
<td>CP15BEN&lt;sup&gt;d&lt;/sup&gt;</td>
<td>CR accesses to the CP15DMB, CP15DSB, and CP15ISB instructions</td>
</tr>
</tbody>
</table>

---

Note
The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

---

a. The controls that are implemented in SCTLR are also implemented in SCTLR_EL1, and apply when PL1 is using AArch64 and PL0 is using AArch32.
b. SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
c. IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
d. System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.
Enabling use of Advanced SIMD and floating-point functionality

Table G1-26 summarizes the controls of Advanced SIMD and floating-point functionality.

**Table G1-26 Controls of use of Advanced SIMD and floating-point functionality**

<table>
<thead>
<tr>
<th>Control</th>
<th>Type</th>
<th>Description, see</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPACR.{cp11, cp10}</td>
<td>E</td>
<td>Enabling PL0 and PL1 accesses to the SIMD and floating-point registers</td>
</tr>
<tr>
<td>FPEXC.EN</td>
<td>E</td>
<td>Enabling access to the SIMD and floating-point registers on page G1-5320</td>
</tr>
<tr>
<td>CPACR.ASEDIS</td>
<td>D</td>
<td>Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-5320</td>
</tr>
</tbody>
</table>

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED. Support for the CPACR.ASEDIS control is optional, and if the control is not implemented behavior is as if the control permits the execution of Advanced SIMD instructions at PL1 and PL0.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-5254.

**Enabling PL0 and PL1 accesses to the SIMD and floating-point registers**

CPACR.{cp11, cp10} enable PL0 and PL1 accesses to the SIMD and floating-point registers.

When CPACR.cp10 is:

- **00**: PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **01**: PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **10**: Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE.
- **11**: This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The value of CPACR.cp11 is ignored. If CPACR.cp11 is programmed with a different value to CPACR.cp10 then CPACR.cp11 is UNKNOWN on a direct read of the CPACR.

---

**Note**

- Software must set CPACR.cp11 and CPACR.cp10 to the same value.

Table G1-27 shows the registers for which accesses are enabled.

**Table G1-27 Register accesses enabled at PL0 and PL1 by CPACR.{cp11, cp10}**

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL0 and PL1, or PL0 only&lt;sup&gt;a&lt;/sup&gt;</td>
<td>FPSCR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

---

<sup>a</sup> Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

<sup>b</sup> Permitted VMSR accesses to the FPSID are ignored, but for the purposes of the {cp10, cp11} controls the architecture defines a VMSR accesses to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, the functionality described in this section is disabled in Non-secure state, and CPACR.{cp11, cp10} are RAZ/WI in Non-secure state. See *Enabling Non-secure access to SIMD and floating-point functionality* on page G1-5346.
For more information about SIMD and floating-point support, see *Advanced SIMD and floating-point support on page G1-5308.*

**Enabling access to the SIMD and floating-point registers**

FPEXC.EN enables accesses to the SIMD and floating-point registers at all Exception levels, but does not control the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

When FPEXC.EN is:

- 1 Accesses to the registers shown in Table G1-28 are enabled at all Exception levels.
- 0 All accesses to the registers shown in Table G1-28 are UNDEFINED.

Table G1-28 shows the registers for which accesses are enabled, and for an exception taken to Hyp mode, how the exception is reported in HSR.

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Exception levels</td>
<td>FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
</tbody>
</table>

a. Only for exceptions that are taken to Hyp mode.

For more information, see *Advanced SIMD and floating-point support on page G1-5308.*

**Disabling PL0 and PL1 execution of Advanced SIMD instructions**

If implemented as an RW field, CPACR.ASEDIS can disable PL0 and PL1 execution of Advanced SIMD instructions, as follows:

- 1 Advanced SIMD instructions are UNDEFINED at PL0 and PL1.
- 0 Advanced SIMD instruction execution is enabled at PL0 and PL1.

The instructions that CPACR.ASEDIS disables are those described in *Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-3548.*

When the control is not implemented, meaning the CPACR.ASEDIS field is RAZ/WI, behavior is as if the control permits execution of Advanced SIMD instructions at PL0 and PL1.

If EL3 is implemented and is using AArch32, and NSACR.NSASEDIS is 1, CPACR.ASEDIS is RAO/WI in Non-secure state. This also applies when the CPACR.ASEDIS control is not implemented.

**Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers**

DBGDSCRxext.UDCCdis traps EL0 accesses to the DCC registers to Undefined mode:

- 1 EL0 accesses to the DCC registers are trapped to Undefined mode
- 0 This control has no effect on EL0 accesses to the DCC registers.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Table G1-29 shows the registers for which accesses are trapped.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>DBGDSCRxint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDSAR, DBGDRAR</td>
</tr>
</tbody>
</table>
All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

### Traps to Undefined mode of EL0 accesses to the Generic Timer registers

CNTKCTL.{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN} trap EL0 accesses to the Generic Timer registers to Undefined mode, as follows:

- **CNTKCTL.PL0PTEN** traps EL0 accesses to the physical timer registers.
- **CNTKCTL.PL0VTEN** traps EL0 accesses to the virtual timer registers.
- **CNTKCTL.PL0PCTEN** traps EL0 accesses to the frequency register and physical counter register.
- **CNTKCTL.PL0VCTEN** traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

Accesses to the frequency register, CNTFRQ, are only trapped if CNTKCTL.PL0PCTEN and CNTKCTL.PL0VCTEN are both 0.

Table G1-30 shows the registers for which accesses are trapped.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL0PTEN</td>
<td>CNTP_CTL, CNTP_CVAL, CNTP_TVAL</td>
</tr>
<tr>
<td>PL0VTEN</td>
<td>CNTV_CTL, CNTV_CVAL, CNTV_TVAL</td>
</tr>
<tr>
<td>PL0PCTEN</td>
<td>CNTFRQ, CNTPCT</td>
</tr>
<tr>
<td>PL0VCTEN</td>
<td>CNTFRQ, CNTVCT</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-5254.

### Traps to Undefined mode of EL0 accesses to Performance Monitors registers

PMUSERENR.{ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to Undefined mode.

For each of these controls:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

For those Performance Monitors registers that more than one PMUSERENR.{ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

- **Note**

  - The architecture does not provide traps on Performance Monitors register accesses through the memory-mapped external debug interface.
  - If the Performance Monitors Extension is not implemented, the Performance Monitors registers, including PMUSERENR, are reserved.
Table G1-31 shows the registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.

**Table G1-31 Register accesses trapped to Undefined mode when disabled from EL0**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Access type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 ER</td>
<td>PMXEVCNTR, PMEVCNTR&lt;\text{n}&gt;</td>
<td>R</td>
<td></td>
</tr>
<tr>
<td></td>
<td>PMSELR</td>
<td>RW</td>
<td></td>
</tr>
<tr>
<td>CR PMCCNTR, accessed using an MRC</td>
<td>R</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CR PMCCNTR, accessed using an MRRC</td>
<td>R</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SW PMSWINC</td>
<td>W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EN PMCNTENSET, PMCNTENCLR, PMCR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCEID2, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMOVSET, PMEVCNTR&lt;\text{n}&gt;, PMEVTYPER&lt;\text{n}&gt;, PMCCFILTR</td>
<td>RW&lt;sup&gt;a&lt;/sup&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<sup>a</sup> The EL0 access is trapped only if the corresponding EL1 accesses is permitted. For example, the PMSWINC register is WO at EL1, and therefore, when the value of EN is 0:
- Write accesses to the register from EL0 are trapped.
- Read accesses to the register from EL0 are UNDEFINED, because read accesses to the register from EL1 are UNDEFINED.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2 on page G1-5254*.

**Traps to Undefined mode of EL0 accesses to Activity Monitors registers**

AMUSERENR.EN traps EL0 accesses to the Activity Monitors System registers other than AMUSERENR to Undefined mode:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

**Note**

- The architecture does not provide traps on Activity Monitors register accesses through the memory-mapped external interface.
- If the Activity Monitors Extension is not implemented, the Activity Monitors registers, including AMUSERENR, are reserved.

Table G1-32 shows the registers for which EL0 accesses are trapped.

**Table G1-32 Register accesses trapped to Undefined mode when disabled from EL0**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>AMCFGFR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0&lt;\text{n}&gt;, AMEVTYPER1&lt;\text{n}&gt;, AMEVCNTR0&lt;\text{n}&gt;, or AMEVCNTR1&lt;\text{n}&gt;</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2 on page G1-5254*. 
G1.21.3 EL2 configurable controls

These controls are ignored in Secure state when using AArch32.

Table G1-33 shows the System registers that contain these controls.

<table>
<thead>
<tr>
<th>Register name</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Trap</td>
<td>Trap controls on page G1-5314</td>
</tr>
</tbody>
</table>

Also see the following:
- Register access instructions on page G1-5315.
- Instructions that fail their Condition code check on page G1-5325.
- Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-5325.
**Instructions that fail their Condition code check**

For **UNDEFINED** instructions that fail their Condition code check, see *Conditional execution of undefined instructions on page G1-5276*.

For an instruction that has a Hyp trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Hyp Trap exception.
  - Executes as a **NOP**.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
  - Always generate a Hyp Trap exception.
  - Always treat the instruction as a **NOP**.

- The IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions on page G1-5276* must be consistent with the handling of Hyp traps on instructions that fail their Condition code check. Table G1-36 shows this:

<table>
<thead>
<tr>
<th>Behavior of conditional <strong>UNDEFINED</strong> instruction&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Hyp trap on instruction that fails its Condition code check&lt;sup&gt;b&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a <strong>NOP</strong></td>
<td>Executes as a <strong>NOP</strong></td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Hyp Trap exception</td>
</tr>
</tbody>
</table>

<sup>a</sup> As defined in *Conditional execution of undefined instructions on page G1-5276*. In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.

<sup>b</sup> For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

---

**Note**

Hyp traps on **WFE** and **WFI** instructions generate Hyp Trap exceptions only if the instruction passes its Condition code check. See *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-5333*.

---

**Trapping to EL2 of instructions that are UNPREDICTABLE**

For an instruction that is **UNPREDICTABLE** or **CONSTRAINED UNPREDICTABLE**, when the instruction is disabled or trapped then it is **CONSTRAINED UNPREDICTABLE** whether execution of the instruction generates a Hyp Trap exception.

---

**Note**

**UNPREDICTABLE** and **CONSTRAINED UNPREDICTABLE** behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not **UNPREDICTABLE** and are not **CONSTRAINED UNPREDICTABLE**. This means that disabling or trapping an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of **UNPREDICTABLE** and **CONSTRAINED UNPREDICTABLE** instructions.

If no instructions are trapped, the attempted execution of an **UNPREDICTABLE** instruction in a Non-secure EL1 or EL0 mode must not generate a Hyp Trap exception.
Disabling or enabling EL2 use of AArch32 deprecated functionality

Table G1-37 shows the deprecated AArch32 functionality that might have disable controls in the HSCTLR:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented, then the associated functionality cannot be disabled.

These HSCTLR controls apply only to execution at EL2 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL2, meaning it is undefined in Hyp mode.

Table G1-37 EL2 controls for disabling and enabling EL2 use of AArch32 deprecated functionality

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the HSCTLR</th>
<th>Disabled instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED&lt;sup&gt;a&lt;/sup&gt;</td>
<td>SETEND instructions</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD&lt;sup&gt;b&lt;/sup&gt;</td>
<td>See the HSCTLR.IT description</td>
</tr>
<tr>
<td>DMB, DSB, and ISB barrier operations</td>
<td>CP15BEN&lt;sup&gt;c&lt;/sup&gt;</td>
<td>MCR accesses to the CP15DMB, CP15DSB, and CP15ISB</td>
</tr>
</tbody>
</table>

<sup>a</sup> SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
<sup>b</sup> IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
<sup>c</sup> System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

--- Note ---
- These controls have no effect on instructions executed in any mode other than Hyp mode. The SCTLR provides similar controls that apply to execution in other modes.
- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

HCR.[TRVM, TVM] trap Non-secure EL1 accesses to the virtual memory control registers to Hyp mode:

**HCR.TRVM, for read accesses:**

- 1: Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode.
- 0: This control has no effect on Non-secure EL1 reads of the virtual memory control registers.

**HCR.TVM, for write access:**

- 1: Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode.
- 0: This control has no effect on Non-secure EL1 writes to the virtual memory control registers.

Table G1-38 on page G1-5327 shows the registers for which:

- Reads are trapped to Hyp mode when HCR.TRVM is 1.
- Writes are trapped to Hyp mode when HCR.TVM is 1.
The table also shows how the exceptions are reported in **HSR**.

### Table G1-38 Register read and write accesses trapped when **HCR.(TRVM, TVM)** are 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, IFAR, AIFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>

**Note**

These registers are not accessible at EL0.

### Disabling Non-secure state execution of **HVC** instructions

**HCR.HCD** disables Non-secure state execution of **HVC** instructions:

1. **HVC** instructions are **UNDEFINED** at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
2. **HVC** instruction execution is enabled at EL2 and Non-secure EL1.

**Note**

**HVC** instructions are always **UNDEFINED** at EL0.

**HCR.HCD** is only implemented if EL3 is not implemented. Otherwise, it is **RES0**. See the **HCR** register description.

### Table G1-39 shows how the exceptions are reported in **HSR**.

### Table G1-39 Instruction that causes exceptions when **HCR.HCD** is 1

<table>
<thead>
<tr>
<th>Attempted execution in</th>
<th>Disables instruction</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>

<tr>
<td>Mode other than Hyp mode</td>
<td><strong>HVC</strong></td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

### Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the System instruction encoding space includes TLB maintenance instructions.

**HCR.TTLB** traps Non-secure EL1 execution of TLB maintenance instructions to Hyp mode:

1. Any attempt to execute a **TLBI** instruction at Non-secure EL1 is trapped to Hyp mode.
2. This control has no effect on the Non-secure EL1 execution of **TLBI** instructions.

Table G1-40 shows the instructions that are trapped, and how the exceptions are reported in **HSR**.

### Table G1-40 Instructions trapped to Hyp mode when **HCR.TTLB** is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TLBIALLIS, TLBIMVAIS, TLBISADIS, TLBIMVAIS, TLBIMVALIS, TLBIMVAALIS, TLBIMVAALIS, ITLBIALLL, ITLBIMVA, ITLBISAD, DTLBIMVA, DTLBISAD, TLBIALLL, TLBIMVA, TLBISAD, TLBIMVAAL, TLBIMVAL, TLBIMVAAL.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>
Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see The scope of TLB maintenance instructions on page G5-5538.

Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

HCR.{TSW, TPC, TPU} trap cache maintenance instructions to Hyp mode:

0  The control has no effect on the execution of cache maintenance instructions.

1  Any attempt to execute one of the cache maintenance instructions shown in Table G1-42 at Non-secure EL1 is trapped to Hyp mode.

Table G1-41 Controls for trapping cache maintenance instructions to Hyp mode

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Trapped instructions</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>TPU</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAC</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see Cache maintenance system instructions on page K13-7440.

Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

HCR.TAC traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode:

1  Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to Hyp mode.

0  This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.

Table G1-43 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-43 Register accesses trapped to Hyp mode when HCR.TAC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>ACTLR and, if implemented, ACTLR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111) access, using EC value 0x03</td>
</tr>
</tbody>
</table>
The ACTLR and ACTLR2 are not accessible at EL0.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR.TIDCP traps the execution of System register access instructions that access these registers, as follows:

1. At Non-secure EL1, any attempt to execute an MCR or MRC instruction with a reserved register encoding shown in Table G1-44 is trapped to Hyp mode.

   At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute MCR or MRC instructions with reserved register encodings are:
   • Trapped to Hyp mode.
   • UNDEFINED, and the PE takes the Undefined Instruction exception to Non-secure Undefined mode.

   Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.

0. This control has no effect on Non-secure EL0 and EL1 System register access instructions with reserved register encodings shown in Table G1-44.

This means that a Hyp Trap exception taken from Non-secure EL1 to Hyp mode, generated because of a configuration setting in HCR.TIDCP is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because the register is never accessible at EL1. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5243 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2.

Table G1-44 shows the register encodings for which accesses are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-44 Encodings trapped to Hyp mode when HCR.TIDCP is 1

</tr>
<tr>
<td></td>
<td>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</td>
<td></td>
</tr>
</tbody>
</table>

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

ARM expects the trapping of Non-secure User mode accesses to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.
Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

HCR.TSC traps Non-secure EL1 execution of SMC instructions to Hyp mode:

1

Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

0

This control has no effect on Non-secure EL1 execution of SMC instructions.

Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are always UNDEFINED at EL0.
- HCR.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap and SMC exceptions have different preferred return addresses.

Table G1-45 shows how the exceptions are reported in HSR:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>SMC on page F5-4257</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see SMC on page F5-4257.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers

Other than the MIDR, MPIDR, and PMCR.N, the ID registers are divided into groups, with a trap control in the HCR for each group.

Table G1-46 ID register groups

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Register group</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TID0</td>
<td>ID group 0, Primary device identification registers on page G1-5331</td>
</tr>
<tr>
<td>HCR.TID1</td>
<td>ID group 1, Implementation identification registers on page G1-5332</td>
</tr>
<tr>
<td>HCR.TID2</td>
<td>ID group 2, Cache identification registers on page G1-5332</td>
</tr>
<tr>
<td>HCR.TID3</td>
<td>ID group 3, Detailed feature identification registers on page G1-5332</td>
</tr>
</tbody>
</table>

These controls trap register accesses from Non-secure EL0 or EL1 to Hyp mode, as follows:

HCR.TID0

0

This control has no effect on Non-secure EL1 reads of the ID group 0 registers.

1

Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to Hyp mode.

HCR.TID1

0

This control has no effect on Non-secure EL1 reads of the ID group 1 registers.

1

Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to Hyp mode.

HCR.TID2

0

This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.

1

Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the CSSELr, is trapped to Hyp mode.
**HCR.TID3**

| 0 | This control has no effect on Non-secure EL1 reads of the ID group 3 registers. |
| 1 | Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to Hyp mode. |

For the MIDR and MPIDR, and for PMCR.N, the architecture provides read/write aliases. The original register becomes accessible only from Hyp mode and Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

**Table G1-47 ID register substitution**

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR</td>
<td>VPIDR</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR</td>
<td>VMPIDR</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR.N</td>
<td>HDCR.HPMN</td>
</tr>
</tbody>
</table>

Reads of the MIDR, MPIDR, or PMCR.N from Hyp mode or Secure state are unchanged by the implementation of EL2, and access the physical registers.

**Note**

- If the optional Performance Monitors Extension is not implemented, HDCR.HPMN is RES0 and PMCR is reserved.
- HDCR.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.
- PMCR contains other fields that identify the implementation. For more information about trapping accesses to the PMCR, see [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers](#) on page G1-5341.

A reset into AArch32 state sets VPIDR to the MIDR value, VMPIDR to the MPIDR value, and HDCR.HPMN to the PMCR.N value.

**ID group 0, Primary device identification registers**

These registers identify some top-level implementation choices.

Table G1-48 shows the registers that are in ID group 0 for traps to Hyp mode, and how the exceptions are reported in HSR.

**Table G1-48 ID group 0 registers**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>FPSID</td>
<td>Trapped VMRS access, for ID group traps, using EC value 0x08</td>
</tr>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>JIDR</td>
<td>Trapped MCR or MRC access (coproc==0b11110), using EC value 0x05</td>
</tr>
</tbody>
</table>

**Note**

The FPSID is not accessible at EL0.

If HCPTR.{TCP11, TCP10} traps accesses to SIMD and floating-point functionality, then for a read of FPSID, that trap has priority over this trap.

When the FPSID is accessible, a VMRS FPSID, <Rt> instruction is permitted but is ignored. The execution of this VMRS instruction is not trapped by the ID group 0 trap.
**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table G1-49 shows the registers that are in ID group 1 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table G1-50 shows the registers that are in ID group 2 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>CTR, CCSIDR, CLIDR, CSSELR, and, if implemented, CCSIDR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.

--- Note ---

These registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See The CPUID identification scheme on page G4-4993.

---

Table G1-51 shows the registers that are in ID group 3 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>MVFR0, MVFR1, MVFR2.</td>
<td>Trapped VMRS access for ID group traps, using EC value 0x08</td>
</tr>
</tbody>
</table>

**ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0.**

**ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4,**

except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.

**ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.**

Any MRC access to any of the following encodings when coproc==0b1111:

- opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0, 1}.
- opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- opc1 == 0, CRn == c0, CRm == c5, opc2 == {4, 5}.

It is IMPLEMENTATION DEFINED whether HCR.TID3 traps MRC accesses with coproc==0b1111 to encodings in the following range that are not already mentioned in this table:

- CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}.

Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03
If HCPTR traps accesses to SIMD and floating-point functionality, then for reads of MVFR0, MVFR1, and MVFR2, that trap has priority over this trap.

**Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions**

HCR.{TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to Hyp mode:

**HCR.TWE:**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.</td>
</tr>
<tr>
<td>0</td>
<td>This control has no effect on Non-secure EL0 or EL1 execution of WFE instructions.</td>
</tr>
</tbody>
</table>

**HCR.TWI:**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.</td>
</tr>
<tr>
<td>0</td>
<td>This control has no effect on Non-secure EL0 or EL1 execution of WFI instructions.</td>
</tr>
</tbody>
</table>

Table G1-52 shows how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>WFE</td>
<td>Trapped WFI or WFE instruction, using EC value 0x01</td>
</tr>
<tr>
<td></td>
<td>WFI</td>
<td></td>
</tr>
</tbody>
</table>

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

**Note**

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait For Event and Send Event* on page G1-5300.
- *Wait For Interrupt* on page G1-5303.

**Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Activity Monitors registers**

If the Activity Monitors Extension is implemented, HCPTR.TAM traps Non-secure EL0 and EL1 accesses to the Activity Monitors registers to Hyp mode:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL0 and EL1 accesses to all Activity Monitors registers are trapped to Hyp mode.</td>
</tr>
<tr>
<td>0</td>
<td>This control has no effect on Non-secure EL0 and EL1 accesses to the Activity Monitors registers.</td>
</tr>
</tbody>
</table>

**Note**

- EL2 does not provide traps on Activity Monitor register accesses through the optional memory-mapped external interface.
- If the Activity Monitors Extension is not implemented, HCPTR.TAM is RES0.
Table G1-53 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

### Table G1-53 Register accesses trapped to Hyp mode when HDCR.{TPM, TPMCR} are 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>TPM</td>
<td>AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPE0&lt;n&gt;, or AMEVTYPE1&lt;n&gt;.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AMEVCNTR0&lt;n&gt;or AMEVCNTR1&lt;n&gt;.</td>
<td>Trapped MCR or MRR access (coproc==0b1111), using EC value 0x04.</td>
</tr>
</tbody>
</table>

### General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers

HCPTR.{TCP11, TCP10} trap Non-secure accesses to the SIMD and floating-point registers to Hyp mode:

- **0b11**: All Non-secure accesses to the SIMD and floating-point registers are trapped to Hyp mode. Trapped instructions generate:
  - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
  - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- **0b00**: This control has no effect on Non-secure accesses to the SIMD and floating-point registers.

---

Note

Software must set HCPTR.TCP11 and HCPTR.TCP10 to the same value.

Table G1-54 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

### Table G1-54 Register accesses trapped to Hyp mode when HCPTR.{TCP11, TCP10} are both 0b11

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-5310.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07a.</td>
</tr>
</tbody>
</table>

### Enabling access to the SIMD and floating-point registers

FPEXC.EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

- VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, then HCPTR.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-5308.

---

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, then HCPTR.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-5308.

### Enabling access to the SIMD and floating-point registers

FPEXC.EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

- VMSR accesses to the FPEXC or FPSID.
- VMSR accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

FPEXC.EN is a PL1 control that also applies at EL2. See Enabling access to the SIMD and floating-point registers on page G1-5320.
Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

If implemented as an RW field, HCPTR.TASE can trap Non-secure execution of Advanced SIMD instructions to Hyp mode, as follows. This trap applies only when HCPTR.{TCP11, TCP10} are both 0:

1

Any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode. Trapped instructions generate:

- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
- Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0

This control has no effect on Non-secure execution of Advanced SIMD instructions.

When the control is not implemented, meaning the HCPTR.TASE field is RAZ/WI, the HCPTR does not provide a trap to Hyp mode of the Non-secure execution of Advanced SIMD instructions, other than the HCPTR.{TCP11, TCP10} trap that applies to Non-secure execution of both Advanced SIMD and floating-point instructions.

Table G1-27 on page G1-5319 shows the instructions that are trapped, and how the exceptions are reported in HSR.

Table G1-55 Instructions trapped to Hyp mode when HCPTR.TASE is set to 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>All Advanced SIMD instructions that are not also floating-point instructions. For more information, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-3548.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch32, and NSACR.NSASEDIS is 1, then HCPTR.TASE behaves as RAO/WI, regardless of its actual value. This behavior also applies when the HCPTR.TASE control is not implemented.

Traps to Hyp mode of Non-secure EL1 accesses to the CPACR

HCPTR.TCPAC traps Non-secure EL1 accesses to the CPACR to Hyp mode:

1

Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.

0

This control has no effect on Non-secure EL1 accesses to the CPACR.

Table G1-56 shows how the exceptions are reported in HSR:

Table G1-56 Register accesses trapped to Hyp mode when HCPTR.TCPAC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>CPACR</td>
<td>Trapped MCR or MRC access to System register with coproc==0b11111, using EC value 0x03</td>
</tr>
</tbody>
</table>

--- Note ---

- The CPACR is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one use of the CPACR is to identify what coprocessor, or conceptual coprocessor, functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism. See Background to the System register interface on page G1-5306 for more information about this functionality.
Traps to Hyp mode of Non-secure System register accesses to trace registers

If implemented, the HCPTR.TTA control traps System register accesses to the trace registers from Non-secure state to Hyp mode, as follows:

1

- Non-secure System register accesses to the trace registers are trapped to Hyp mode. Trapped instructions generate:
  - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
  - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0

This control has no effect on Non-secure System register accesses to the trace registers.

If the HCPTR.TTA control is not implemented, then HCPTR.TTA is RAO/WI. See the register description for more information.

--- Note ---

- System register accesses to the trace registers use the System register (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than an HCPTR.TTA Hyp Trap exception.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side effects. When a System register access is trapped, no side effects occur before the exception is taken, see Register access instructions on page G1-5315.

Table G1-57 shows the registers for which accesses are trapped to Hyp mode when HCPTR.TTA is 1, and how the exceptions are reported in HSR.

### Table G1-57 Register accesses trapped to Hyp mode when HCPTR.TTA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
</table>
| Non-secure state | System register accesses to all implemented trace registers | For accesses using:
| | | • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. |
| | | • MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, then HCPTR.TTA behaves as RAO/WI, regardless of its actual value. This behavior applies, also, when the HCPTR.TTA control is not implemented.

Traps to Hyp mode of Non-secure System register accesses to trace filter control registers

If implemented, the HDCR.TTRF control traps System register accesses to the trace filter control registers from Non-secure state to Hyp mode, as follows:

1

- Non-secure System register accesses at EL1 to the trace filter control registers are trapped to Hyp mode. Trapped instructions generate Hyp Trap exceptions.

0

This control has no effect on Non-secure System register accesses to the trace registers.
Table G1-58 shows the registers for which accesses are trapped to Hyp mode when HDCR.TTRF is 1, and how the exceptions are reported in HSR.

### Table G1-58 Register accesses trapped to Hyp mode when HDCR.TTRF is 1

<table>
<thead>
<tr>
<th>Traps from Non-secure state</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRFCR</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03.</td>
<td></td>
</tr>
</tbody>
</table>

**General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space**

HSTR.\{T0-T3, T5-T13, T15\} trap Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, or MRRC instructions, to the System registers in the (coproc==0b1111) encoding space, by:

- The value of the CRn argument to the instruction, for MCR and MRC instructions.
- The value of the CRm argument to the instruction, for MCRR and MRRC instructions.

This applies for the set of CRn, or CRm, values \{c0-c3, c5-c13, c15\}.

When an HSTR.Tn trap control is:

1

- Non-secure EL1 accesses to the corresponding System registers in the (coproc==0b1111) encoding space are trapped to Hyp mode.
- EL0 accesses to the corresponding System registers are trapped to Hyp mode if they would not be UNDEFINED if the bit was zero.

0

- This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

**Note**

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in HSTR.Tn, is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because a register is never accessible at Non-secure EL1. As **Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5243** shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2. This prioritization includes any access from Non-secure EL1 to a register that is only accessible in Secure state. So, for example, an access to the SCR from Non-secure EL1:

- When the value of HSTR.T1 is 0, generates an Undefined Instruction exception.
- When the value of HSTR.T1 is 1, generates a Hyp Trap exception.

Table G1-59 shows the accesses that are trapped, and how the exceptions are reported in HSR.

### Table G1-59 Accesses trapped to Hyp mode when an HSTR.Tn trap is enabled

<table>
<thead>
<tr>
<th>Traps from Non-secure EL0 and EL1</th>
<th>Trap control</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCR and MRC instructions, with coproc set to 0b1111 and CRn set to n</td>
<td>MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MCR and MRC instructions, with coproc set to 0b1111 and CRm set to n</td>
<td>MCR or MRC access (coproc==0b1111), using EC value 0x04</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

a. As described in this section, traps from EL1 apply whenever the value of HSTR.Tn is 1. Traps from EL0 apply only if the value of HSTR.Tn is 1 and the access would not be UNDEFINED if the value of HSTR.Tn was 0.

For example, when HSTR.T7 is 1, considering only accesses from Non-secure EL1:

- Any 32-bit access from a Non-secure PL1 mode using an MRC or MCR instruction with coproc set to 0b1111 and CRn set to c7, is trapped to Hyp mode.
The AArch32 System Level Programmers’ Model

G1.21 Configurable instruction enables and disables, and trap controls

- Any 64-bit access from a Non-secure PL1 mode using an MRRR or MCRR instructions with coproc set to 0b1111 and CRm set to c7, is trapped to Hyp mode.

--- Note ---
- Bits[4,14] of the HSTR are reserved, RES0. Although the Generic Timer control registers are implemented in the coproc == 0b1111 encoding space with CRn == c14 for an MRC or MCR access, EL2 does not provide a trap on accesses to the Generic Timer System registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of trapping of IMPLEMENTATION DEFINED features.

System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0

For a System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a HSTR.Tn control, if an access to the register from User mode is UNDEFINED when the value of the corresponding HSTR.Tn trap control is 0, then when that HSTR.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:
- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

--- Note ---
ARM expects that trapping to Hyp mode of Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

Traps to Hyp mode of Non-secure System register accesses to debug registers

HDCR.{TDRA, TDOSA, TDA} trap Non-secure System register accesses to debug registers to Hyp mode, as follows:
- HDCR.(TDRA, TDA) trap Non-secure EL0 and EL1 accesses.
- HDCR.TDOSA traps Non-secure EL1 accesses.

--- Note ---
EL2 does not provide traps of debug register accesses through the optional memory-mapped external debug interface.

System register accesses to the debug registers can have side effects. When a System register access is trapped to Hyp mode, no side effects occur before the exception is taken to Hyp mode. See Register access instructions on page G1-5315.

Table G1-60 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in HSR.

### Table G1-60 Traps of Non-secure EL0 and EL1 accesses to debug registers

<table>
<thead>
<tr>

<tr>
<td>HDCR.TDOSA</td>
<td>Trapping Non-secure System register accesses to powerdown debug registers on page G1-5339</td>
</tr>
<tr>
<td>HDCR.TDA</td>
<td>Trapping general Non-secure System register accesses to debug registers on page G1-5339</td>
</tr>
</tbody>
</table>
Note

System register accesses to debug registers use the (coproc == \text{0b1110}) encoding space.

**Trapping Non-secure System register accesses to Debug ROM registers**

HDCR.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode:

1. Non-secure EL0 or EL1 System register accesses to the Debug ROM registers are trapped to Hyp mode.
2. This control has no effect on Non-secure EL0 and EL1 System register accesses to the Debug ROM registers.

Table G1-61 shows the register accesses that are trapped, and how the exceptions are reported in HSR:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>DBGDRAR, DBGDSAR</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- MCR or MRC instructions, trapped MCR or MRC access (coproc == \text{0b1110}), using EC value \text{0x05}.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- MRRC instructions, trapped MRRC access (coproc == \text{0b1110}), using EC value \text{0x0C}.</td>
</tr>
</tbody>
</table>

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDRA is 1 other than for the purpose of a direct read.

**Trapping Non-secure System register accesses to powerdown debug registers**

HDCR.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode:

1. Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.
2. This control has no effect on Non-secure EL1 System register accesses to the powerdown debug registers.

Table G1-62 shows the register accesses that are trapped, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR</td>
<td>Any IMPLEMENTATION DEFINED integration registers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Trapped MCR or MRC access (coproc == \text{0b1110}), using EC value \text{0x05}.</td>
</tr>
</tbody>
</table>

Note

These registers are not accessible at EL0.

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDOSA is 1 other than for the purpose of a direct read.

**Trapping general Non-secure System register accesses to debug registers**

HDCR.TDA traps Non-secure EL0 and EL1 System register accesses to the debug registers that are not mentioned in either of the following:

- Traps to Hyp mode of Non-secure System register accesses to debug registers on page G1-5338.
- Trapping Non-secure System register accesses to powerdown debug registers.
This means that HDCR.TDA traps to Hyp mode Non-secure EL0 and EL1 System register accesses to all debug registers except the following:

- Non-secure System register accesses to DBGDAR or DBGDSAR. The HDCR.TDRA trap traps these accesses.
- Non-secure System register access to DBGOSLSR, DBGOSLAR, DBGOSDLR, or DBGPRCR. The HDCR.TDOSA trap traps these accesses.

HDCR.TDA does not trap accesses to DBGDTRTXint or DBGDTRRXint when the PE is in Debug state.

When HDCR.TDA is:

1  Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table G1-63 are trapped to Hyp mode.
0  This control has no effect on Non-secure EL0 or EL1 System register accesses.

Table G1-63 shows how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from Non-secure EL0 and EL1</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Accesses to the DBGDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRxext, DBGDTRTXext, DBGDTRRXext, DBGVCR, DBGWCR, DBGWCRxext, DBGWCR&lt;n&gt;, DBGWVCR&lt;n&gt;, DBGWVCR&lt;n&gt;, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGSECCR</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
<tr>
<td>STC accesses to DBGDTRRXint.</td>
<td></td>
<td>Trapped LDC or STC access, using EC value 0x06</td>
</tr>
<tr>
<td>LDC accesses to DBGDTRTXint.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDA is 1 other than for the purpose of a direct read.

**Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers**

CNTHCTL.{PL1PCEN, PL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to Hyp mode, as follows:

- CNTHCTL.PL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL.PL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

1  This control has no effect on Non-secure EL0 and EL1 accesses to the registers shown in Table G1-64 on page G1-5341.
0  Non-secure EL0 and EL1 accesses are trapped to Hyp mode.
Table G1-64 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

### Table G1-64 Register accesses trapped to Hyp mode by CNTHCTL trap controls

<table>
<thead>
<tr>
<th>Traps from</th>

### Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

If the Performance Monitors Extension is implemented, HDCR.{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to Hyp mode:

**HDCR.TPM:**

1. Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
2. This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors registers.

**HDCR.TPMMC:**

1. Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.
   
   **Note**
   
   The conditions for this trap are identical to those for the trap controlled by HDCR.TPM.

2. This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers.

**Note**

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, HDCR.{TPM, TPMCR} are RES0.
Table G1-65 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

### Table G1-65 Register accesses trapped to Hyp mode when HDCR.(TPM, TPMCR) are 1

<table>

Also see the following:

- *Register access instructions* on page G1-5315.
- *Instructions that fail their Condition code check.*
- *Trapping to EL3 of instructions that are UNPREDICTABLE* on page G1-5344.

**Instructions that fail their Condition code check**

For UNDEFINED instructions that fail their Condition code check, see *Conditional execution of undefined instructions* on page G1-5276.

For an instruction that has a Monitor trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Monitor Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Monitor trap is set on such an instruction it must either:
  - Always generate a Monitor trap exception.
  - Always treat the instruction as a NOP.
The IMPLEMENTATION DEFINED part of the requirements of Conditional execution of undefined instructions on page G1-5276 must be consistent with the handling of Monitor traps on instructions that fail their Condition code check. Table G1-70 shows this:

Table G1-70 Consistent handling of instructions that fail their Condition code check

<table>
<thead>
<tr>
<th>Behavior of conditional UNDEFINED instruction</th>
<th>Monitor trap on instruction that fails its Condition code check</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Generates a Monitor trap exception</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Monitor trap exception</td>
</tr>
</tbody>
</table>

a. As defined in Conditional execution of undefined instructions on page G1-5276. In Non-secure EL0 and EL1 modes, this applies only if no Monitor trap is set for the instruction, otherwise see the behavior in the other column of the table.

b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

---

Trapping to EL3 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Monitor Trap exception.

---

UNPREDICTABLE and constrained unpredictable behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not constrained unpredictable. This means that disabling or trapping an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE and constrained unpredictable instructions.

---

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode must not generate a Monitor Trap exception.

Traps to Monitor mode of the execution of wFE and wFI instructions in modes other than Monitor mode

SCR{TWE, TWI} trap wFE and wFI instructions to Monitor mode:

**SCR.TWE**

<table>
<thead>
<tr>
<th>1</th>
<th>Any attempt to execute a wFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>This control has no effect on the execution of wFE instructions.</td>
</tr>
</tbody>
</table>

**SCR.TWI**

<table>
<thead>
<tr>
<th>1</th>
<th>Any attempt to execute a wFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>This control has no effect on the execution of wFI instructions.</td>
</tr>
</tbody>
</table>

For PL0 and PL1, these traps apply to wFE and wFI instruction execution in both Security states.

The attempted execution of a conditional wFE or wFI instruction is only trapped if the instruction passes its Condition code check.
Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- Wait For Event and Send Event on page G1-5300.
- Wait For Interrupt on page G1-5303.

Traps to Monitor mode of accesses to RAS error record registers

SCR.TERR traps accesses to the RAS ER* registers from modes other than Monitor mode to Monitor mode.

Table G1-71 Register accesses trapped to EL3 when SCR.TERR is 1

<table>
<thead>
<tr>
<th>Traps from AArch32 state</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTRLR, ERXCTRLR2, EXFR, EXFR2, ERXMSC0, ERXMSC1, ERXMSC2, ERXMSC3, ERXMSC4, ERXMSC5, ERXMSC6, ERXMSC7, ERXSTATUS.</td>
<td>For accesses using:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC access, (coproc==0b1111) using EC value 0x04</td>
<td></td>
</tr>
</tbody>
</table>

This trap control applies to accesses from both Security states.

Enabling EL2 and Non-secure EL1 execution of HVC instructions

SCR.HCE enables EL2 and Non-secure EL1 execution of HVC instructions:

1  

HVC instruction execution is enabled at EL2 and Non-secure EL1.

0  

HVC instructions are:

- UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken to Undefined mode.
- CONSTRAINED UNPREDICTABLE at EL2. The behavior must be one of the following:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

Note

- If EL2 is not implemented, SCR.HCE is RES0 and HVC is UNDEFINED.
- HVC instructions are always UNDEFINED at EL0 and in Secure state.

Disabling SMC instructions

SCR.SCD disables SMC instructions:

1  

In Non-secure state  

SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

In Secure state  

Behavior is one of the following:

- The instruction is UNDEFINED.
• The instruction executes as a NOP.

0  SMC instructions are enabled.

--- Note ---
• SMC instructions are always UNDEFINED at EL0.
• When the value of HCR.TSC is 1, any attempted execution of an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR.SCD, see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-5330. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5243 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to a higher Exception level.

Disabling Non-secure System register access to the trace registers
NSACR.NSTRCDIS disables Non-secure System register accesses to the trace registers, from all Privilege levels:

1  Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
   • CPACR.TRCDIS behaves as RAO/WI, regardless of its actual value. See Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-5318.
     This behavior applies even if the CPACR.TRCDIS control is not implemented. See the referenced section for more information.
   • HCPTR.TTA behaves as RAO/WI, regardless of its actual value. See Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-5336.

0  There is no effect on accesses to CPACR.TRCDIS and HCPTR.TTA.

--- Note ---
• System register accesses to the trace registers use the (coproc==0b1111) encoding space.
• NSACR.NSTRCDIS might be implemented as RAZ/WI. See the NSACR register description for more information.
• The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
• EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

Traps to Monitor mode of System register accesses to the trace filter control registers
SDCR.TTRF traps any System register accesses to trace filter control registers to Monitor mode:

1  Any attempt to access a trace filter control register in any mode other than Monitor mode is trapped to Monitor mode.

0  This control has no effect.

Enabling Non-secure access to SIMD and floating-point functionality
NSACR.{cp11, cp10} enable Non-secure access to the SIMD and floating-point registers, from all Privilege levels:

0b11  All accesses, from both Security states, are enabled.
Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:

- CPACR.{cp11, cp10} behave as RAZ/WI. See *Enabling PL0 and PL1 accesses to the SIMD and floating-point registers* on page G1-5319.
- HCPTR.{TCP11, TCP10} behave as RAO/WI. See *General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers* on page G1-5334.

**Note**
Software must set NSACR.cp11 and NSACR.cp10 to the same value.

For more information about SIMD and floating-point support, see *Advanced SIMD and floating-point support* on page G1-5308.

### Disabling Non-secure access to Advanced SIMD functionality

NSACR.NSASEDIS disables Non-secure accesses to the Advanced SIMD functionality, from all Privilege levels:

- Non-secure state accesses are disabled. Secure accesses are enabled. If the PE is in Non-secure state:
  - CPACR.ASEDIS behaves as RAO/WI. See *Disabling PL0 and PL1 execution of Advanced SIMD instructions* on page G1-5320.
  - HCPTR.TASE behaves as RAO/WI. See *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-5335.

  These behaviors apply even if one or both of the CPACR.ASEDIS and HCPTR.TASE controls is not implemented. See the referenced sections for more information.

- There is no effect on CPACR.ASEDIS and HCPTR.TASE.

#### Pseudocode description of configurable instruction enables, disables, and traps

The pseudocode function `AArch32.CheckITEnabled()` checks whether the T32 IT instruction is enabled.

The pseudocode function `AArch32.CheckSETENDEnabled()` checks whether the SETEND instruction is disabled.

The pseudocode function for `AArch32.CheckForSMCUndefOrTrap()` checks for traps on an SMC instruction.

The `AArch32.CheckForWFxTrap()` pseudocode function checks for traps on `WFE` and `WFI` instructions:

### Pseudocode description of enabling SIMD and floating-point functionality

The `AArch32.CheckAdvSIMDOrFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The `CheckAdvSIMDOrFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckFPEnabled()` wrapper functions support the `AArch32.CheckAdvSIMDOrFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` functions.

The `AArch32.CheckAdvSIMDOrFPEnabled()`, `AArch32.CheckFPAdvSIMDTrap()`, `CheckAdvSIMDOrFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckFPEnabled()` functions are described in *Chapter J1 ARMv8 Pseudocode*. 
G1 The AArch32 System Level Programmers’ Model
G1.21 Configurable instruction enables and disables, and trap controls
When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

**Introductory information**
- About self-hosted debug on page G2-5350.
- The debug exception enable controls on page G2-5354.

**The debug Exception model**
- Routing debug exceptions on page G2-5355.
- Enabling debug exceptions from the current Privilege level and Security state on page G2-5357.
- The effect of powerdown on debug exceptions on page G2-5359.
- Summary of permitted routing and enabling of debug exceptions on page G2-5360.
- Pseudocode description of debug exceptions on page G2-5362.

**The debug exceptions**
- Breakpoint Instruction exceptions on page G2-5363.
- Breakpoint exceptions on page G2-5366.
- Watchpoint exceptions on page G2-5391.
- Vector Catch exceptions on page G2-5405.

**Synchronization requirements**
The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a *Context synchronization event* guarantees the effects of the changes:
- Synchronization and debug exceptions on page G2-5412.
G2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in:

• Chapter D1 The AArch64 System Level Programmers’ Model, if the exception is taken to AArch64 state.
• Chapter G1 The AArch32 System Level Programmers’ Model, if the exception is taken to AArch32 state.

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

• Definition of a debugger in the context of self-hosted debug.
• Context ID and Process ID.

G2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

G2.1.2 Context ID and Process ID

In AArch32 state, the CONTEXTIDR identifies the current Context ID, that is used by:

• The debug logic, for breakpoint and watchpoint matching.
• Implemented trace logic, to identify the current process.

When using the Long-descriptor translation table format, the CONTEXTIDR has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical when using this translation table format.

When using the Short-descriptor translation table format:

• CONTEXTIDR[31:0] defines the Context ID, that is used for breakpoint and watchpoint matching.
• CONTEXTIDR[31:8] defines the Process ID.
• CONTEXTIDR[7:0] define the ASID. See Global and process-specific translation table entries on page G5-5525. This means that, when using the Short-descriptor translation table format, the ASID is always bits[7:0] of the Context ID.

G2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 stage 1 translation regime are:

• Breakpoint Instruction exceptions on page G2-5351.
• Breakpoint exceptions on page G2-5351, generated by hardware breakpoints.
• Watchpoint exceptions on page G2-5352, generated by hardware watchpoints.
• Vector Catch exceptions on page G2-5352.

Note

In addition, Software Step exceptions can be generated in stage 1 of an AArch32 translation regime. However, these are always taken to AArch64 state. Software Step exceptions on page D2-2284 describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
2. A debugger has enabled that particular debug exception.

   All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the DBGDSCRnext. See The debug exception enable controls on page G2-5354.

   ― ― Note  ― ―

   If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

   For the definition of halting is allowed, see Halting allowed and halting prohibited on page H2-6417.

   When a debug exception is taken to an Exception level that is using AArch32:
   • If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
   • Otherwise, it is taken as a Prefetch Abort exception.

   The following list summarizes each of the debug exceptions:

   **Breakpoint Instruction exceptions**

   Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

   The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

   **PE behavior**

   Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:
   • The current Privilege level and AArch32 mode.
   • The current Security state.

   For more information, see Breakpoint Instruction exceptions on page G2-5363.

   **Breakpoint exceptions**

   The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

   For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

   The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:
   • Address:
     — Address Match.
     — Address Mismatch.

   Comparisons are made with the virtual address of each instruction in the program flow.

   • Context:
     — Context ID Match. Matches with the Context ID value held in the CONTEXTIDR.
     — VMID Match. Matches with the VMID value held in the VTTBR.

   An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.
A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions on page G2-5366.*

**Watchpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions on page G2-5391.*

**Vector Catch exceptions**

These are used to trap exceptions. The ARMv8-A architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the DBGVCR. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

**PE behavior**

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see *Vector Catch exceptions on page G2-5405.*

Table G2-1 on page G2-5353 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.
### Table G2-1 PE behavior and pseudocode for each of the debug exceptions

</tbody>
</table>

a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.
G2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

DBGDSCRext.MDBGen, plus an enable control for each breakpoint, DBGBCR<n>.E.

**Watchpoint exceptions**

DBGDSCRext.MDBGen, plus an enable control for each watchpoint, DBGWCR<n>.E.

**Vector Catch exceptions**

DBGDSCRext.MDBGen.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Privilege level and Security state* on page G2-5357.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
G2.3 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, if EL2 is implemented, the routing of debug exceptions depends on the Effective values of HDCR.TDE and HCR.TGE:

If the Effective value of \{HDCR.TDE, HCR.TGE\} is not \{0, 0\}

Debug exceptions taken from Non-secure state are routed to Hyp mode.

If EL2 is using AArch64 and ARMv8.4-secEL2 is implemented, debug exceptions taken from Secure EL0 and Secure EL1 may be routed to Secure EL2. For more information, see Routing debug exceptions on page D2-2287.

Otherwise

In Non-secure state debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure Abort mode.
- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
- All other debug exceptions are disabled from Hyp mode.

Note

If EL2 is not implemented, the Effective value of HCR.TGE is 0 and the Effective value of HDCR.TDE is 0.

Table G2-2, Table G2-3, and Table G2-4 on page G2-5356 show the routing of debug exceptions taken from an Exception level that is using AArch32 to an Exception level that is using AArch32. In these tables:

- TDE Means the logical OR of HDCR.TDE and HCR.TGE.
- (Hyp mode) Means:
  - All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Privilege level.
  - Breakpoint Instruction exceptions taken from this Privilege level are taken to Hyp mode.

### Table G2-2 Routing when both EL3 and EL2 are implemented

<table>

G2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level. `DebugTargetFrom()` returns the debug target Exception level for the specified Security state.
G2.4 Enabling debug exceptions from the current Privilege level and Security state

A debug exception can only be taken if all of the following are true:

• The OS Lock is unlocked.
• DoubleLockStatus() == FALSE.
• The debug exception is enabled from the current Privilege level.
• The debug exception is enabled from the current Security state.

Table G2-5 shows when debug exceptions are enabled from the current Privilege level.

<table>
<thead>
<tr>
<th>Current Privilege level</th>

<td>Depends on SDCR.SPD and SDER.SUIDEN.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See Disabling debug exceptions from Secure state.</td>
</tr>
</tbody>
</table>

G2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can enable or disable all debug exceptions taken from Secure PL1 other than Breakpoint Instruction exceptions, by using one of:

• The Secure Privileged Debug field, SDCR.SPD, if EL3 is using AArch32.
• The AArch32 Secure Privileged Debug field, MDCR_EL3.SPD32, if EL3 is using AArch64.

If debug exceptions are disabled from Secure PL1, software executing at Secure PL1 can set the Secure User Invasive Debug Enable bit, SDER.SUIDEN, to 1 to enable all debug exceptions taken from Secure PL0 other than Breakpoint Instruction exceptions.

Note

Breakpoint Instruction exceptions are always enabled.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

Note

If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.

G2.4.2 Pseudocode description of enabling debug exceptions

AArch64.GenerateDebugExceptions() determines whether debug exceptions are enabled from the current Exception level and Security state. AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions are enabled from the specified Exception level and Security state.
G2 AArch32 Self-hosted Debug
G2.4 Enabling debug exceptions from the current Privilege level and Security state
G2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-6525 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and DoubleLockStatus() == FALSE.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
G2.6  Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Privilege level and Security state. Table G2-7 shows the routing of these. In the table, n/a means not applicable.

Table G2-7 Routing of Breakpoint Instruction exceptions

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>HDCR.TDEa</th>
<th>Target when enabled from:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>PL0</td>
</tr>
<tr>
<td>Secure</td>
<td>X</td>
<td>Secure Abort modeb</td>
</tr>
<tr>
<td>Non-secure</td>
<td>0</td>
<td>Non-secure Abort mode</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Hyp mode</td>
</tr>
</tbody>
</table>

a. If EL2 is not implemented, behavior is as if the value of this bit is 0. Otherwise, if the value of HCR.TGE is 1, HDCR.TDE is treated as being 1 other than for a direct read of HDCR.

b. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

**All other debug exceptions**

The enabling and permitted routing is controlled by all of the following:

- SDCR.SPD.
- SDER.SUIDEN.
- HDCR.TDE.
- The IMPLEMENTATION DEFINED authentication interface.

Table G2-8 shows the valid combinations of the values of SDCR.SPD, SDER.SUIDEN, HDCR.TDE, and, in the Auth column, the input from the IMPLEMENTATION DEFINED authentication interface described by the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled(). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table G2-8 Breakpoint, Watchpoint, and Vector Catch exceptions (continued)

| Debug state | Locka | Current Security state | SPDb | Authc | SUIDEN | TDEd | | | | Target AArch32 mode when enabled from: |
|-------------|-------|------------------------|------|-------|--------|------| | | | PL0 | PL1 | PL2 |
| No | FALSE | Secure | 0b10 | X | l | X | Secure Abort modee | - | n/a |
| No | FALSE | Secure | 0b11 | X | X | X | Secure Abort modee | Secure Abort modee | n/a |
| No | FALSE | Non-secure | 0bXX | X | X | 0 | Non-secure Abort mode | Non-secure Abort mode | - |
| No | FALSE | Non-secure | 0bXX | X | X | l | Hyp mode | Hyp mode | - |

a. The value of (OSLSR_EL1.OSLK == 1 || DoubleLockStatus()).
b. If EL3 is not implemented, behavior is as if this is 0b11.
c. See the text that introduces this table for an explanation of the Auth on page G2-5360 column. An entry of TRUE indicates that the authentication mechanism permits the debug exceptions to be taken to their default target PE mode.
d. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.
e. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.
G2.7 Pseudocode description of debug exceptions

AArch32.DebugFault() returns a FaultRecord() that indicates that a memory access has generated a debug exception.

The AArch32.Abort() function processes FaultRecord(), as described in Abort exceptions on page G4-5454, and generates:

• Data Abort exceptions for watchpoints.
• Prefetch Abort exceptions for all other debug exceptions.
G2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

--- Note ---

When the PE is executing in EL0 using AArch32 and EL1 is using AArch64, it is using the AArch64 EL1&0 translation regime. A T32 or A32 BKPT instruction executed at EL0 can generate a Breakpoint Instruction exception that is taken to an Exception level that is using AArch64. For more information about the handling of these exceptions, see Breakpoint Instruction exceptions on page D2-2294.

---

It contains the following subsections:

- About Breakpoint Instruction exceptions.
- Breakpoint instruction in the A32 and T32 instruction sets.
- BKPT instructions as the first instruction in an IT block on page G2-5364.
- Exception syndrome information and preferred return address for a BKPT instruction on page G2-5364.
- Pseudocode description of Breakpoint Instruction exceptions on page G2-5365.

G2.8.1 About Breakpoint Instruction exceptions

A **breakpoint** is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a **hardware breakpoint**.
- The instruction itself. That is, the instruction is a **breakpoint instruction**. These can be included in the program that the PE executes. This type of breakpoint is called a **software breakpoint**.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page G2-5366 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D, is using AArch64 or AArch32.

--- Note ---

- EL_D is the Exception level that debug exceptions are targeting. See Enabling debug exceptions from the current Privilege level and Security state on page G2-5357.
- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-94.

---

G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:

- BKPT #<immediate>

For details of the instruction encoding, see BKPT on page F5-3875.

**About whether the BKPT instruction is conditional**

In the T32 instruction set, BKPT instructions are always unconditional.

In the A32 instruction set:

- If the Condition code field is AL, the BKPT instruction is unconditional.
• If the Condition code field is anything other than AL, behavior is CONSTRAINED UNPREDICTABLE, and is one of the following:
  — The instruction is UNDEFINED.
  — The instruction is treated as a NOP instruction.
  — The instruction is executed unconditionally.
  — The instruction is executed conditionally.

G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

0  The BKPT instruction generates a Breakpoint Instruction exception.
1  The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception.

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

HSCTRL.ITD  Applies to execution at EL2 when EL2 is using AArch32.
SCTRL.ITD   Applies to execution at EL0 or EL1 when EL1 is using AArch32.
SCTRL_EL1.ITD Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note

T32 BKPT instructions are always unconditional, even when they are inside an IT block. See:

• Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-5317.
• Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-5326.

G2.8.4 Exception syndrome information and preferred return address for a BKPT instruction

See the following:

• Exception syndrome information for a Breakpoint Instruction exception.
• Preferred return address for a Breakpoint Instruction exception on page G2-5365.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Breakpoint Instruction exception

The PE takes a Breakpoint Instruction exception as either:

• A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
• A Hyp Trap exception, if it is taken to PL2 because either HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

• DBGDSCRext.MOE to 0b0011, to indicate a Breakpoint Instruction exception.
**PL2 Hyp mode**

The PE does all of the following:

- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-9.
- Sets DBGDSRext.MOE to \(0b0001\), to indicate a Breakpoint Instruction exception.
- Sets the HIFAR to an unknown value.

**Preferred return address for a Breakpoint Instruction exception**

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

### Table G2-9 Information recorded in the HSR

<table>

**Note**

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-5355.

### G2.8.5 Pseudocode description of Breakpoint Instruction exceptions

```c
AArch32.SoftwareBreakpoint() generates a Prefetch Abort exception that is taken from AArch32 state.
```
G2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
• At EL1 or higher in an Exception level that is using AArch32.
• At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page G2-5367.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.
• Breakpoint instruction address comparisons on page G2-5378.
• Breakpoint context comparisons on page G2-5383.
• Using breakpoints on page G2-5384.
• Exception syndrome information and preferred return address for a Breakpoint exception on page G2-5389.
• Pseudocode description of Breakpoint exceptions taken from AArch32 state on page G2-5390.

G2.9.1 About Breakpoint exceptions

A **breakpoint** is an event that results from the execution of an instruction, based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a **hardware breakpoint**.
• The instruction itself. That is, the instruction is a **breakpoint instruction**. These can be included in the program that the PE executes. This type of breakpoint is called a **software breakpoint**.

**Breakpoint exceptions** are generated by **Breakpoint debug events**. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in **Breakpoint Instruction exceptions** on page G2-5363.

An implementation can include between 2-16 hardware breakpoints. DBGIDR.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The **Breakpoint Control Register**, DBGBCR<\(n\)>. This contains controls for the breakpoint, for example an enable control.
• The **Breakpoint Value Register**, DBGBVR<\(n\)>. This holds a value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
• If EL2 is implemented, the **Breakpoint Extended Value Register**, DBGBXVR<\(n\)> , that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:
• DBGBCR1, DBGBVR1, and DBGBXVR1 are for breakpoint number one.
• DBGBCR2, DBGBVR2, and DBGBXVR2 are for breakpoint number two.
• ...
• DBGBCR<\(n\)> , DBGBVR<\(n\)> , and DBGBXVR<\(n\)> are for breakpoint number <\(n\)>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:
• The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<\(n\)> .E, is 1.
The conditions specified in the DBGBCR<n> are met.

The comparisons with the values held in one or both of the DBGBV<n> and DBGX<n>, as applicable, are successful.

If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.

The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are enabled, Breakpoint debug events generate Breakpoint exceptions. Otherwise, Breakpoint debug events are ignored.

--- Note ---

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions. However, the behavior described also applies if breakpoints are causing entry to Debug state.

---

The debug exception enable controls on page G2-5354 describes the enable controls for Breakpoint debug events.

## G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - An instruction address mismatch.
  - A Context ID match, with the value held in the CONTEXTIDR.
  - A VMID match, with the value held in the VTTBR.
  - Both a Context ID match and a VMID match.

- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

DBGDIDR.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a Linked Address Match breakpoint.
2. Program breakpoint number five to be a Linked Context ID Match breakpoint.

3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The Breakpoint Type field for a breakpoint, DBGBCR<n>.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-5378.

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

• Only Linked breakpoint types can be linked.

• Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<n>.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  — DBGBCR<n>.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.
  — DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

• Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

• Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

• If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page G2-5388.

• If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

• Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page G2-5391 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

• Multiple Linked Address Match breakpoints.
• Multiple Linked Address Mismatch breakpoints.
• Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it. Figure G2-1 on page G2-5369 shows an example of permitted breakpoint and watchpoint linking.
In Figure G2-1, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn.BT**

The following list provides more detail about each breakpoint type:

**0b0000, Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- \( \text{DBGBCR}<n>.\{\text{SSC, HMC, PMC}\} \). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-5375.

- A successful address match, as described in *Breakpoint instruction address comparisons* on page G2-5378.

\( \text{DBGBCR}<n>.\text{LBN} \) for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>.{SSC, HMC, PMC}** for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.

- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons on page G2-5378.

- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<n>.LBN** for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>.{SSC, HMC, PMC}**. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.

- A successful Context ID match, as described in Breakpoint context comparisons on page G2-5383.

The value of **DBGBVR<n>.ContextID** is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes ARMv8.1-VHE.

- EL2 is implemented and enabled in the current Security state.

- EL2 using AArch64 and the value of **HCR_EL2.E2H** is 1.

- The PE is executing at EL0 and **HCR_EL2.TGE** is 1, or the PE is executing at EL2.

Otherwise, **CONTEXTIDR** holds the current Context ID.

**DBGBCR<n>.{LBN, BAS}** for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.

- Generation of a Breakpoint exception depends on both:
  
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-5378.

  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

- Generation of a Watchpoint exception depends on both:

  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-5395.

  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

The value of **DBGBVR<n>.ContextID** is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes ARMv8.1-VHE.

- EL2 is implemented and enabled in the current Security state.

- EL2 using AArch64 and the value of **HCR_EL2.E2H** is 1.
• The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
Otherwise, CONTEXTIDR holds the current Context ID.
DBGBCR<n>.{LBN, SSC, HMC, BAS PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.
• A successful address mismatch, as described in Breakpoint instruction address comparisons on page G2-5378.
DBGBCR<n>.LBN for this breakpoint is ignored.

0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.
• A successful address mismatch defined by this breakpoint, as described in Breakpoint instruction address comparisons on page G2-5378.
• A successful context match defined by the Linked Context breakpoint that this breakpoint links to.
DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0110 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

The Context ID check is made against the value in CONTEXTIDR, or CONTEXTIDR_EL1. The value of DBGVR<n>.ContextID is compared with the Context ID value held in CONTEXTIDR or CONTEXTIDR_EL1.
DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0111 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-5378.
— A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

- Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-5395.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

The Context ID check is made against the value in CONTEXTIDR, or CONTEXTIDR_EL1. The value of DBGVR<n>.ContextID is compared with the Context ID value held in CONTEXTIDR or CONTEXTIDR_EL1.

DBGCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
- DBGCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5375.
- A successful VMID match, as described in Breakpoint context comparisons on page G2-5383.

DBGCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1001 is a reserved value if either:
- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:
- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page G2-5378.
  — A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-5395.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-5383.

DBGCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.
For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-5375.

- A successful Context ID match, as described in *Breakpoint context comparisons* on page G2-5383.

- A successful VMID match.

The value of DBGBVR<n>.ContextID is compared with CONTEXTIDR.

*Breakpoint context comparisons* on page G2-5383 describes the requirements for a successful Context ID match and a successful VMID match.

**DBGBCR<n>**.{LBN, BAS} for this breakpoint are ignored.

0b1011, **Linked Context ID and VMID Match breakpoint**

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.

- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page G2-5378.
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-5383.
  - A successful VMID match defined by this breakpoint.

- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page G2-5395.
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-5383.
  - A successful VMID match defined by this breakpoint.

The value of DBGBVR<n>.ContextID is compared with CONTEXTIDR.

*Breakpoint context comparisons* on page G2-5383 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

**DBGBCR<n>**.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1100, **Unlinked CONTEXTIDR_EL2 Match breakpoint**

BT == 0b1100 is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.

- A successful CONTEXTIDR_EL2 match. The value of DBGBVR<n>.ContextID2 is compared with the Context ID value held in CONTEXTIDR_EL2, as described in *Breakpoint context comparisons* on page G2-5383.
The check against CONTEXTIDR_EL2 means this breakpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1101, Linked CONTEXTIDR_EL2 Match

BT == 0b1101 is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.
- EL2 is not implemented.

For context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-5378.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page G2-5383.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-5395.
  - A successful CONTEXTIDR_EL2 match. The value of DBGBV<n>.ContextID2 is compared with the Context ID value held in CONTEXTIDR_EL2, as described in Breakpoint context comparisons on page G2-5383.

The check against the CONTEXTIDR_EL2 means the breakpoint or watchpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1110, Unlinked Full Context ID Match breakpoint

BT == 0b1110 is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons on page G2-5383.

The Context ID check is made by checking both:

- The value of DBGBV<n>.ContextID against the value in CONTEXTIDR, or CONTEXTIDR_EL1.
- The value of DBGBXV<n>.ContextID2 against the value in CONTEXTIDR_EL2.

Both comparisons must match for the check to succeed.
The check against the CONTEXTIDR_EL2 means this breakpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1111, Linked Full Context ID Match breakpoint

BT == 0b1111 is a reserved value if:
  • The breakpoint is not a context-aware breakpoint.
  • The implementation does not include ARMv8.1-VHE.
  • EL2 is not implemented.

For context-aware breakpoints, one of the following applies:
  • If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
  • Generation of a Breakpoint exception depends on both:
    — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-5378.
    — A successful Context ID match, as described in Breakpoint context comparisons on page G2-5383.
  • Generation of a Watchpoint exception depends on both:
    — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-5395.
    — A successful Context ID match, as described in Breakpoint context comparisons on page G2-5383.

The Context ID check is made by checking both:
  • The value of DBGVR<n>.ContextID against the value in CONTEXTIDR, or CONTEXTIDR_EL1.
  • The value of DBGXVR<n>.ContextID2 against the value in CONTEXTIDR_EL2.

Both comparisons must match for the check to succeed.

The check against the CONTEXTIDR_EL2 means the breakpoint or watchpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

--- Note ---
See Reserved DBGBCR<n>.BT values on page G2-5386 for the behavior of breakpoints programmed with reserved BT values.

---

G2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.
DBGBCR<n>.{SSC, HMC, PMC} define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

**Security State Control, SSC**
Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

--- Note -----
This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**
HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

Table G2-10 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

- **Y** Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row can generate Breakpoint exceptions in AArch32 modes at that Privilege level.

- **-** Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

- **Res** Means that the combination of HMC, SSC, and PMC is reserved. See Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-5387.

a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.

b. Only in User, System and Supervisor modes.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See [Reserved HMC, SSC, and PMC combinations](#) on page G2-5387.
### Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- Address Match breakpoints.
- Address Mismatch breakpoints.

#### Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to `DBGBVR<n>[31:2].`
- The word or halfword selected by `DBGBCR<n>.BAS` matches. That is, either:
  - `DBGBCR<n>.BAS` is programmed with `0b0011` or `0b1111`, and the instruction is at a word-aligned address.
  - `DBGBCR<n>.BAS` is programmed with `0b1100`, and the instruction is not at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

#### Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to `DBGBVR<n>[31:2].`
- The word or halfword selected by `DBGBCR<n>.BAS` does not match. That is, either:
  - `DBGBCR<n>.BAS` is programmed with `0b0011` or `0b1111`, and the instruction is not at a word-aligned address.
  - `DBGBCR<n>.BAS` is programmed with `0b1100`, and the instruction is at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

#### Note

- `DBGBVR<n>[1:0]` are RES0 and are ignored.

---

#### Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the Byte Address Selection field, `DBGBCR<n>.BAS`, so that the address comparison is successful on one of:

- The whole word starting at address `DBGBVR<n>[31:2]:00`.
- The halfword starting at address `DBGBVR<n>[31:2]:00`.
- The halfword starting at address `((DBGBVR<n>[31:2]:00) + 2)`.

---

#### Note

The address programmed into the `DBGBVR<n>` must be word-aligned.
DBGBCR\textsubscript{<n>}.BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, DBGBCR\textsubscript{<n>}.BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
  - The instruction address held in bits [31:2] of the DBGBVR\textsubscript{<n>}.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = DBGBVR\textsubscript{<n>}[31:2] match AND BAS match.

- For an Address Mismatch breakpoint, DBGBCR\textsubscript{<n>}.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
  - The instruction address held in bits [31:2] of the DBGBVR\textsubscript{<n>}.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = NOT (DBGBVR\textsubscript{<n>}[31:2] match AND BAS match).

The following subsections show the supported BAS values:

- Using the BAS field in Address Match breakpoints.
- Using the BAS field in Address Mismatch breakpoints on page G2-5381.

For Context breakpoints, DBGBCR\textsubscript{<n>}.BAS is RES1 and is ignored.

**Using the BAS field in Address Match breakpoints**

The supported BAS values are:

- **0b0000**
  
  This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:
  - The breakpoint is disabled.
  - The breakpoint behaves as if BAS is 0b0011, 0b1100, or 0b1111.

- **0b0011**
  
  The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR\textsubscript{<n>}[31:2].
  - Bits [1:0] of the address are 0b00.

  This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:
  - 32-bit T32 instructions at word-aligned addresses.
  - 16-bit T32 instructions at word-aligned addresses.
  - A32 instructions. These are always at word-aligned addresses.

  However, ARM recommends that a debugger uses this BAS value only for T32 instructions. It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR\textsubscript{<n>}[31:2]:00) - 2).

- **0b1100**
  
  The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR\textsubscript{<n>}[31:2].
  - Bits [1:0] of the address are 0b10.

  This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:
  - 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  - 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

  It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.
The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<\n>[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<\n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<\n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<\n>.BAS[3,1] ignore writes and read the same values as DBGBCR<\n>[2,0] respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-2 on page G2-5381 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address ((DBGBVR<\n>[31:2]:00) + 2).
- Row 6 shows that a breakpoint with a BAS value of either 0b0011 or 0b1111 generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

- **Yes** Means that the breakpoint generates a Breakpoint exception.
- **No** Means that the breakpoint does not generate a Breakpoint exception.
- **UNP** Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-5388.
Figure G2-2 Summary of BAS field meanings for Address Match breakpoints

Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

0b0000 The breakpoint ignores the address held in the DBGBVR<n> and generates Breakpoint exceptions for all instruction addresses.

0b0011 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  • Bits [31:2] of the address equals DBGBVR<n>[31:2].
  • Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:
  • 32-bit T32 instructions at word-aligned addresses.
  • 16-bit T32 instructions at word-aligned addresses.
  • A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

0b1100 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  • Bits [31:2] equals DBGBVR<n>[31:2].
  • Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
  • 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  • 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

0b1111 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  • Bits [31:2] equals DBGBVR<n>[31:2].
  • Bits [1:0] of the address are 0b11.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
  • 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  • 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

0b1110 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  • Bits [31:2] equals DBGBVR<n>[31:2].
  • Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
  • 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  • 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

The solid areas show the location of the instruction.
It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

0b1111

The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

• Bits [31:2] of the address equals DBGBVR<n>[31:2].
• Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

• 32-bit T32 instructions at word-aligned addresses.
• 16-bit T32 instructions at word-aligned addresses.
• A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

Figure G2-3 on page G2-5383 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

• A column showing the row number, on the left.
• An instruction set and instruction size table.
• A location of instruction figure.
• A BAS field values table, on the right.

To use the figure, read across the rows. For example:

• Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the DBGBVR<n>.
• Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the DBGBVR<n>.

In the figure:

| Yes | Means that the breakpoint does generate a Breakpoint exception. |
| No | Means that the breakpoint does not generate a Breakpoint exception. |
| UNP | Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-5388. |
### G2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>.BT determines what context comparison is required, if any. Table G2-11 shows the BT values that require a comparison, and the match required for the comparison to be successful.

![Table G2-11 Breakpoint Context ID and VMID comparison tests](image)

- **DBGBCR<n>.BT**
  - **0b001x**: When ARMv8.1-VHE is implemented, EL2 is using AArch64, the **Effective value** of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGVR<n>. ContextID value. Otherwise, CONTEXTIDR must match the DBGVR<n>. ContextID value.
  - **0b011x**: CONTEXTIDR, or CONTEXTIDR_EL1, must match the DBGVR<n>. ContextID value.
  - **0b100x**: VTTBR.VMID must match the DBGXVR<n>. VMID value.
  - **0b101x**: CONTEXTIDR, or CONTEXTIDR_EL1, must match the DBGVR<n>. ContextID value, and VTTBR.VMID must match the DBGXVR<n>. VMID value.
  - **0b110x**: CONTEXTIDR_EL2 must match the DBGXVR<n>. ContextID2 value.
  - **0b111x**: Both:
    - CONTEXTIDR, or CONTEXTIDR_EL1, must match the DBGVR<n>. ContextID value.
    - CONTEXTIDR_EL2 must match the DBGXVR<n>. ContextID2 value.

No context comparison is required for other valid DBGBCR<n>.BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR, or CONTEXTIDR_EL1, and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - ARMv8.1-VHE is implemented, EL2 is using AArch64, EL2 is implemented and enabled in the current Security state, and HCR_EL2.{E2H, TGE} == {1, 1}.

- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - ARMv8.1-VHE is not implemented.
— EL2 is either not implemented or not enabled in the current Security state.
— EL2 is using AArch32.

• The comparison uses the current VMID value and any of:
  — EL2 is not implemented.
  — EL2 is either not implemented or not enabled in the current Security state.
  — The PE is executing at EL2.
  — ARMv8.1-VHE is implemented, EL2 is using AArch64, EL2 is implemented and enabled in the current Security state, and HCR_EL2.{E2H, TGE} == {1, 1}.

Note
• For all Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.
• For Linked Context breakpoints, DBGBCR<n>.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

G2.9.6 Using breakpoints

This section contains the following:
• Using an Address Mismatch breakpoint to single-step an instruction.
• ITD control effects on address breakpoints on the first instruction in an IT block on page G2-5385.
• Breakpoint usage constraints on page G2-5386.

Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by DBGBCR<n>.{LBN, SSC, PMC}, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. Figure G2-4 shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address 0x1014.

![Figure G2-4 Operation of an Address Mismatch breakpoint](image)

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in Figure G2-4:
• If the target of a branch is an instruction other than the instruction at address 0x1014, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
• If the target of a branch is the instruction at address 0x1014, the PE executes the instruction at 0x1014 and the breakpoint does not generate a Breakpoint exception until the instruction at address 0x1018 is committed for execution. The instruction at address 0x1014 is therefore single-stepped.
However, if the instruction at 0x1014 generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

— If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address 0x1014. This means that software execution steps into the exception.

— If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at 0x1014 or the instruction at 0x1018.

If the instruction at 0x1014 is single-stepped and branches to itself, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in Figure G2-4 on page G2-5384, this is 0x1014.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of an AArch64 Software Step exception.

Note

• The example shown in Figure G2-4 on page G2-5384 assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.

• Software Step exceptions are the highest priority synchronous exception. Breakpoint exceptions are lower priority. See Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191.

ITD control effects on address breakpoints on the first instruction in an IT block

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

• An IT instruction can only be used to apply to one 16-bit T32 instruction.

• Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.

• For a permitted combination, it is IMPLEMENTATION DEFINED whether the implementation treats the combination as:
  — A pair of 16-bit instructions.
  — One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in Other usage constraints for Address breakpoints on page G2-5388, an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, ARM recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.
**SCTLR.ITD**  Applies to execution at EL0 or EL1 when EL1 is using AArch32.

**SCTLR_EL1.ITD**  Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

--- **Note** ---

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

### Breakpoint usage constraints

See the following sections:

- *Reserved DBGBCR<n>.BT values.*
- *Reserved DBGBCR<n>.{SSC, HMC, PMC} values* on page G2-5387.
- *Reserved DBGBCR<n>.BAS values* on page G2-5387.
- *Reserved DBGBCR<n>.LBN values* on page G2-5388.
- *Other usage constraints for Address breakpoints* on page G2-5388.
- *Other usage constraints for Context breakpoints* on page G2-5388.

**Reserved DBGBCR<n>.BT values**

Table G2-12 shows when particular DBGBCR<n>.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>Context ID Match</td>
<td>If the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b010x</td>
<td>Address Mismatch</td>
<td>If EDSCR.HDE is 1 and halting is allowed</td>
</tr>
<tr>
<td>0b011x</td>
<td>CONTEXTIDR_EL1 Match</td>
<td>If ARMv8.1-VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b100x</td>
<td>VMID Match</td>
<td>If EL2 is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b101x</td>
<td>Context ID and VMID Match</td>
<td></td>
</tr>
<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 Match</td>
<td>If ARMv8.1-VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b111x</td>
<td>Full Context ID Match</td>
<td>For these BT values, breakpoints are not generated if EL2 is using AArch32.</td>
</tr>
</tbody>
</table>

--- **Note** ---

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>.

- For a direct or external read of DBGBCR<n>, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.
The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR\(n\).{SSC, HMC, PMC} values**

Table G2-13 shows when particular combinations of DBGBCR\(n\).{SSC, HMC, PMC} are reserved in stage 1 of an AArch32 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero.</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.</td>
<td>When EL2 is not implemented.</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 and PMC set to 0b01 or 0b1.</td>
<td>When Secure EL2 is not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00.</td>
<td>When Secure EL2 is not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table G2-10 on page G2-5376.</td>
<td>Always.</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR\(n\).{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR\(n\).{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of DBGBCR\(n\).{SSC, HMC, PMC} returns UNKNOWN values.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR\(n\).BAS values**

For all Context breakpoints

DBGBCR\(n\).BAS is RES1 and is ignored.

For all Address breakpoints

The supported values of the BAS field for the Address Match and Address Mismatch breakpoints are shown in Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-5378.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
— Programmed with a BAS value that is not reserved, other than for a direct or external read of 
DBGBCR<n>.

• A direct or external read of DBGBCR<n>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of 
the architecture.

Reserved DBGBCR<n>.LBN values

For all Context breakpoints

DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address 
breakpoint, any DBGBCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not 
context-aware, then reads of DBGBCR<n>.LBN return an unknown value and the behavior is 
CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

• Disabled.
• Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is 
context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it 
behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

• DBGBVR<n>[1:0] are RES0 and are ignored.
• The DBGBXVR<n> is ignored.

For Address Match breakpoints

• For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not 
the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint 
generates a Breakpoint exception.
• If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint 
generates a Breakpoint exception for a T32 instruction starting at address 
((DBGBVR<n>[31:2]:00) + 2). For T32 instructions, ARM recommends that the debugger 
programs the BAS field with either 0b0011 or 0b1100.

For Address Mismatch breakpoints

The constraints are the same as those described in For Address Match breakpoints, except that if 
two Address Mismatch breakpoints are programmed to match in the same Exception level and 
Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a 
Breakpoint debug even is generated.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n> and DBGBXVR<n> that are not used to specify Context ID or VMID 
are RES0 and are ignored.
Note

This means that for Context ID Match breakpoints, the \textit{DBGBXVR<n> is RES0 and is ignored}, and for VMID Match breakpoints, the \textit{DBGBVR<n> is RES0 and is ignored}.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

G2.9.7 Exception syndrome information and preferred return address for a Breakpoint exception

See the following:

\begin{itemize}
  \item Exception syndrome information for a Breakpoint exception.
  \item Preferred return address for a Breakpoint exception on page G2-5390.
\end{itemize}

Note

Usually, the term \textit{exception syndrome} is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Breakpoint exception

The PE takes a Breakpoint exception as either:

\begin{itemize}
  \item A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
  \item A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.
\end{itemize}

If the exception is taken to:

\begin{description}
  \item[Abort mode] The PE sets all of the following:
    \begin{itemize}
      \item DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
      \item IFSR.FS to the code for a debug exception, 0b00010.
      \item The IFAR with an UNKNOWN value.
    \end{itemize}
  \item[Hyp mode] The PE does all of the following:
    \begin{itemize}
      \item Records information about the exception in the \textit{Hypervisor Syndrome Register, HSR}. See Table G2-14.
      \item Sets DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
      \item Sets the HIFAR to an unknown value.
    \end{itemize}
\end{description}

Table G2-14 Information recorded in the HSR

<table>
<thead>
<tr>
<th>HSR field</th>

  \begin{itemize}
    \item ISS[24:10] RES0.
    \item ISS[9] \textit{External Abort type (EA)}. The PE sets this to 0.
    \item ISS[8:6] RES0.
    \item ISS[5:0] \textit{Instruction Fault Status Code (IFSC)}. The PE sets this to the code for a debug exception, 0b100010.
  \end{itemize} |
Preferred return address for a Breakpoint exception

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.9.8  Pseudocode description of Breakpoint exceptions taken from AArch32 state

AArch32.BreakpointValueMatch() returns a pair of results:
- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

AArch32.StateMatch() tests the values in DBGBCR<n>.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch32.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch32.CheckBreakpoint() generates a FaultRecord. A Breakpoint exception is taken if all of the following are true:

- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-5357.
- All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page G2-5366.

Note
AArch32.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The AArch32.Abort() function processes the FaultRecord object returned by AArch32.CheckBreakpoint(), as described in Abort exceptions on page G4-5454. When a Breakpoint exception is taken to AArch32 state, the AArch32.Abort() function generates a Prefetch Abort exception.
G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- About Watchpoint exceptions.
- Watchpoint types and linking of watchpoints on page G2-5392.
- Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-5393.
- Watchpoint data address comparisons on page G2-5395.
- Determining the memory location that caused a Watchpoint exception on page G2-5398.
- Watchpoint behavior on other instructions on page G2-5399.
- Usage constraints on page G2-5400.
- Exception syndrome information and preferred return address on page G2-5402.
- Pseudocode description of Watchpoint exceptions taken from AArch32 state on page G2-5403.

G2.10.1 About Watchpoint exceptions

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, DBGDIDR.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The Watchpoint Control Register, DBGWCR<n>. This holds control information for the watchpoint, for example an enable control.
- The Watchpoint Value Register, DBGWVR<n>. This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:

- DBGWCR1 and DBGWVR1 are for watchpoint number one.
- DBGWCR2 and DBGWVR2 are for watchpoint number two.
- ...
- ...
- DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<n>.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page G2-5396.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the MASK field, DBGWCR<n>.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page G2-5397.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint exceptions is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page G2-5401.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>.E, is 1.
- The conditions specified in the DBGWCR<n> are met.
- The comparison with the address held in the DBGWVR<n> is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See on page G2-5369 shows this. See also Breakpoint context comparisons on page G2-5383.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:
- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions. However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page G2-5354 describes the enable controls for Watchpoint debug events.

G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an Unlinked watchpoint.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a Linked watchpoint.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a Linked VMID Match breakpoint.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, DBGWCR<n>.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<n>.WT is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.

- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGWCR<n>.LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>.WT.{SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.

- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See Usage constraints on page G2-5400.

- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.

- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

  Note
  Multiple Address breakpoints can also link to a single Linked Context breakpoint. Breakpoint exceptions on page G2-5366 describes breakpoints.

Figure G2-1 on page G2-5369 shows an example of permitted watchpoint linking.

G2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

DBGWCR<n>.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

  Note
  This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level or Privilege level at which the access was made.
**Note**

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on PL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are LDRT and STRT.

Table G2-15 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

- **Y** or **-**
  - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
    - **Y**  Can generate Watchpoint exceptions at that Privilege level.
    - **-**  Cannot generate Watchpoint exceptions at that Privilege level.

- **Res**
  - Means that the combination of HMC, SSC, and PAC is reserved. See *Reserved DBGWCR<n>.{SSC, HMC, PAC} values* on page G2-5400.

### G2.10.4 Watchpoint data address comparisons

An address comparison is successful if bits [31:2] of the current data virtual address are equal to \( \text{DBGWVR}<n>[31:2] \), taking into account all of the following:

- The size of the access. See Size of the data access.
- The bytes selected by \( \text{DBGWVR}<n>\.\text{BAS} \). See Programming a watchpoint with eight bytes or fewer on page G2-5396.
- Any address ranges indicated by \( \text{DBGWVR}<n>\.\text{MASK} \). See Programming a watchpoint with eight or more bytes on page G2-5397.

Note

\( \text{DBGWVR}<n>[1:0] \) are RES0 and are ignored.

### Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See Example G2-1.

**Example G2-1**

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by \( \text{DCIMVAC} \) instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that \( \text{CTR}.\text{DminLine} \) defines.
  - 2KB.
- A power-of-two.
The lowest address accessed by a `DCIMVAC` instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by DCIMVAC instructions* on page G2-5400.

### Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>` is:

- Doubleword-aligned:
  - All eight bits of `DBGWCR<n>.BAS` are used, and the descriptions given in Table G2-16 apply.
- Word-aligned but not doubleword-aligned:
  - Only `DBGWCR<n>.BAS[3:0]` are used, and the descriptions given in Table G2-17 apply. In this case, `DBGWCR<n>.BAS[7:4]` are RES0.

#### Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>

<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:111 is accessed</td>
</tr>
</tbody>
</table>

#### Table G2-17 Supported BAS values when the DBGWVRn address alignment is word

<table>
<thead>
<tr>
<th>BAS valuea</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:2]:00 is accessed</td>
</tr>
<tr>
<td>BAS[1] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:2]:01 is accessed</td>
</tr>
<tr>
<td>BAS[2] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:2]:10 is accessed</td>
</tr>
<tr>
<td>BAS[3] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:2]:11 is accessed</td>
</tr>
</tbody>
</table>

a. `DBGWCR<n>.BAS[7:4]` are RES0.
If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page G2-5402.

When programming the BAS field with anything other than \(0b11111111\), a debugger must also program \(\text{DBGWCR}<n>\).MASK to be \(0b000000\). See Programming dependencies of the BAS and MASK fields on page G2-5401.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the \(\text{DBGWVR}<n>[31:3]\). See Example G2-1 on page G2-5395.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - \(\text{DBGWVR}<n>\) with 0x1000.
  - \(\text{DBGWCR}<n>_\text{EL1}.\text{BAS}\) to be \(0b00001000\).

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - \(\text{DBGWVR}<n>\) with 0x2000.
  - \(\text{DBGWCR}<n>_\text{EL1}.\text{BAS}\) to be \(0b00111000\).

- If the address programmed into the \(\text{DBGWVR}<n>\) is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program \(\text{DBGWCR}<n>\.\text{BAS}\) to be \(0b00001111\).
  - To generate a Watchpoint exception when any byte in the word starting at address \(\text{DBGWVR}<n>[31:3]:100\) is accessed, program \(\text{DBGWCR}<n>\.\text{BAS}\) to be \(0b11110000\).

---

**Note**

ARM deprecates programming a \(\text{DBGWVR}<n>\) with an address that is not doubleword-aligned.

---

### Programming a watchpoint with eight or more bytes

A debugger can use the \(\text{MASK}\) field, \(\text{DBGWCR}<n>\.\text{MASK}\), to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.

- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>
If \( n \) least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address \( \text{DBGWVR}<n>[31:n]:000\ldots \)
- Address \( \text{DBGWVR}<n>[31:n]:111\ldots \)
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between \( \text{DBGWVR}<n>[31:4]:0000 \) and \( \text{DBGWVR}<n>[31:4]:1111 \), including these addresses.

**Note**

- The most significant bit cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR<n>.MASK values* on page G2-5402.

When masking address bits, a debugger must both:

- Program \( \text{DBGWCR}<n>.BAS \) to be \( 0b11111111 \). See *Programming dependencies of the BAS and MASK fields* on page G2-5401.
- In the \( \text{DBGWVR}<n> \), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints* on page G2-5402.

**G2.10.5 Determining the memory location that caused a Watchpoint exception**

On a Watchpoint exception, the PE records an address in a Fault Address Register that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- DFAR, if the exception is taken to PL1.
- HDFAR, if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

**Note**

If Debug state was entered from AArch32 state, then \( \text{EDWAR}[63:32] \) is **UNKNOWN** and must be ignored by the debugger.

For more information, see the subsections that follow. These are:

- Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions.
- Address recorded for Watchpoint exceptions generated by data cache maintenance instructions on page G2-5399.

**Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions**

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
— No larger than 2KB.
— No larger than the block size used by the A64 DC ZVA instruction.

Note

There are no architectural means to discover the A64 DC ZVA instruction block size from AArch32 state.

— Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example G2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

• 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
• 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

G2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

• Instruction cache maintenance instructions.
• Address translation instructions.
• TLB maintenance instructions.
• Preload instructions.
• All data cache maintenance instructions except DCIMVAC.
• If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a DC IVAC instruction can generate a Watchpoint.

However, the debug architecture allows for implementation defined controls, such as those in ACTLR registers, to enable watchpoints on an implementation defined subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache maintenance, address translation, and TLB maintenance instructions are implementation defined.

The access size of the IMPLEMENTATION DEFINED instruction cache maintenance, address translation, and TLB maintenance instructions that generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:

• Watchpoint behavior on accesses by Store-Exclusive instructions.
• Watchpoint behavior on accesses by DCIMVAC instructions on page G2-5400.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

• If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
• Otherwise, the watchpoint generates a Watchpoint exception.

**Watchpoint behavior on accesses by DCIMVAC instructions**

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

10 Match on data stores only.
11 Match on data stores and data loads.

--- Note ---

For the size of data accesses performed by DCIMVAC instructions, see Watchpoint data address comparisons on page G2-5395. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

**G2.10.7 Usage constraints**

See the following:

- Reserved DBGWCR<n>.{SSC, HMC, PAC} values.
- Reserved DBGWCR<n>.LBN values on page G2-5401.
- Programming dependencies of the BAS and MASK fields on page G2-5401.
- Reserved DBGWCR<n>.BAS values on page G2-5401.
- Reserved DBGWCR<n>.MASK values on page G2-5402.
- Other usage constraints on page G2-5402.

**Reserved DBGWCR<n>.{SSC, HMC, PAC} values**

Table G2-18 shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b1 and PMC set to 0b00.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero.</td>
<td>When both of EL2 and EL3 are not implemented.</td>

</tr>
</tbody>
</table>

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>.

- For a direct or external read of DBGWCR<n>, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGWCR<n>.LBN values**

**For Linked watchpoints**

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked watchpoints**

For Unlinked watchpoints, DBGWCR<n>.LBN reads UNKNOWN and its value is ignored.

**Programming dependencies of the BAS and MASK fields**

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be \(0b11111111\), so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be \(0b00000\), so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to \(0b11111111\), then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

**Reserved DBGWCR<n>.BAS values**

The BAS field must be programmed with a value \(Zeros(8-n-m):Ones(n):Zeros(m)\), where:

- \(n\) is a non-zero positive integer less-than-or-equal-to 8.
- \(m\) is a positive integer less-than 8.
- \(n+m\) is less-than-or-equal-to 8.

All other values are reserved.

---

**Note**

If \(x\) is zero, then \(Zeros(x)\) is an empty bitstring.

---

If DBGWVR<n>[2] is 1, DBGWCR<n>.BAS[7:4] are RES0 and are ignored.
If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<\n>.
- A direct or external read of DBGWCR<\n>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

**Reserved DBGWCR<\n>.MASK values**

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of DBGWCR<\n>.
- A direct or external read of DBGWCR<\n>.MASK returns an UNKNOWN value.

**Other usage constraints**

For all watchpoints:

- DBGWVR<\n>[1:0] are RES0 and are ignored.
- If DBGWCR<\n>.MASK is nonzero, and any masked bits of DBGWVR<\n> are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<\n>.LSC is 0b00.

**G2.10.8 Exception syndrome information and preferred return address**

See the following:

- Exception syndrome information.
- Preferred return address on page G2-5403.

**Exception syndrome information**

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

**Abort mode**

The PE sets all of the following:

- DBGDSCRext.MOE to 0b1010, to indicate a Watchpoint exception.
- DFSR.CM to indicate whether a cache maintenance instruction caused the exception.
- DFSR.WnR to indicate whether the exception was generated on a read instruction or a write instruction.
- DFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See Determining the memory location that caused a Watchpoint exception on page G2-5398.
In addition, if using the:

- Short-descriptor format, the PE sets DFSR.FS to the code for a debug exception, 0b00010, and DFSR.Domain to an UNKNOWN value.
- Long-descriptor format, the PE sets DFSR.STATUS to the code for a debug exception, 0b100010.

**Hyp mode**

The PE does all of the following:

- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-19.
- Sets DBGDSCRext.MOE to 0b1001, to indicate a Watchpoint exception.
- Sets the HDFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See Determining the memory location that caused a Watchpoint exception on page G2-5398.

---

</tr>
</tbody>
</table>

---

**Note**

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-5355.

---

**Preferred return address**

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

---

**G2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch32 state**

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch32.StateMatch()` tests the values in `DBGWCR<n>`: `{HMC, SSC, PAC}`, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch32.WatchpointMatch()` tests the value in `DBGWVR<n>`.
AArch32.CheckWatchpoint() generates a FaultRecord. A Watchpoint exception is taken if all of the following are true:

- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-5357.
- All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions on page G2-5391.

Note

AArch32.CheckWatchpoint might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The AArch32.Abort() function processes the FaultRecord object returned by AArch32.CheckWatchpoint(), as described in Abort exceptions on page G4-5454. If a Watchpoint exception is taken to AArch32 state, the AArch32.Abort() function generates a Data Abort exception.
G2.11 Vector Catch exceptions

ARM deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

**Note**

Vector Catch exceptions cannot be generated when the PE is using an AArch64 translation regime.

This section contains the following subsections:
- About Vector Catch exceptions.
- Exception vectors that Vector Catch exceptions can be enabled for on page G2-5407.
- Generation of Vector Catch exceptions on page G2-5408.
- Usage constraints on page G2-5410.
- Exception syndrome information and preferred return address for a Vector Catch exception on page G2-5410.
- Pseudocode description of Vector Catch exceptions on page G2-5411.

G2.11.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the exception vector for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the address-matching form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the exception-trapping form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The ARMv8-A architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The DBGDEVID indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the DBGVCR. This register contains vector catch enable bits. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

**Note**

EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the DBGVCR32_EL2. The DBGVCR32_EL2 is architecturally mapped to the DBGVCR.

When Vector Catch exceptions are enabled for an exception vector, this is called an enabled vector catch. The set of exception vectors that Vector Catch exceptions are enabled for is called the enabled vector catch set.

If the form of vector catch implemented is the:

**Address-matching form:**

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.
Exception-trapping form

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

• Address-matching form, the current Security state.
• Exception-trapping form, the Security state that the exception is handled in.

See Generation of Vector Catch exceptions on page G2-5408.

Table G2-20 summarizes the differences between the address-matching and exception-trapping forms.

Table G2-20 Differences in behavior of the address-matching and exception-trapping forms of vector catch

<table>
<thead>
<tr>
<th>Address-matching</th>
<th>Exception-trapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution. This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector. A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.</td>
<td>An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector. This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.</td>
</tr>
<tr>
<td>A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch. Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191 describes this prioritization.</td>
<td>A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it. For this reason, Vector Catch exceptions are outside the scope of the prioritization that Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2191 describes.</td>
</tr>
<tr>
<td>A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.</td>
<td>Vector Catch exceptions must be taken before other exceptions.</td>
</tr>
<tr>
<td>A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.</td>
<td>Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the AArch32 exception handling mode.</td>
</tr>
<tr>
<td>If HCR.TGE is 1, Vector Catch exceptions can be generated for User mode instruction fetches from Non-secure PL1 vectors.</td>
<td>If HCR.TGE is 1, Vector Catch exceptions are never generated in Non-secure state, because: • Exceptions are routed away from Non-secure PL1 vectors, to PL2. • The architecture does not provide vector catch enable bits for the Hyp exception vectors.</td>
</tr>
</tbody>
</table>

Depending on the implementation, some vector catch enable bits in the DBGVCR might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See Exception vectors that Vector Catch exceptions can be enabled for on page G2-5407 for the vector catch enable bits that exist for different implementations.

The debug exception enable controls on page G2-5354 describes the enable controls for Vector Catch exceptions.
G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a vector table at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- Local exception vectors.
- Non-secure Local exception vectors.
- Secure Local exception vectors.
- Hyp exception vectors.
- Monitor exception vectors.

Table G2-21 shows which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Vector table or tables implemented</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 EL1 EL2 EL3</td>
<td></td>
</tr>
<tr>
<td>32 32 - -</td>
<td>Local exception vectors.</td>
</tr>
<tr>
<td>64 -</td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>32 -</td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Hyp exception vectors.</td>
</tr>
<tr>
<td>- 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>- 32</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Monitor exception vectors.</td>
</tr>
<tr>
<td>64 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>32 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Hyp exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Monitor exception vectors.</td>
</tr>
</tbody>
</table>

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the DBGVCR:

- Table G2-22 on page G2-5408 shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
• Table G2-23 on page G2-5408 shows the Monitor exception vectors that Vector Catch exceptions can be enabled for.

The ARMv8-A architecture does not provide vector catch enable bits for the Hyp exception vectors.

### Table G2-22 Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for

<table>
<thead>
<tr>
<th>Vector catch enable bit</th>

<td>MVBAR + 0x0000000C</td>
</tr>
<tr>
<td>MS</td>
<td>Secure Monitor Call</td>
<td>MVBAR + 0x00000008</td>
</tr>
</tbody>
</table>

**Note**

There is no vector catch enable bit for Monitor trap exceptions.

### G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- **Address-matching form.**
- **Exception-trapping form** on page G2-5409.

#### Address-matching form

The PE compares the virtual address of each instruction in the program flow is with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.
• If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

In this case, Table G2-24 shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>For exceptions taken to:</th>
<th>Non-secure PL1 modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>Secure Local exception vectors</td>
<td></td>
</tr>
<tr>
<td>AArch32</td>
<td>Secure Local exception vectors</td>
<td>and Monitor exception vectors</td>
</tr>
</tbody>
</table>

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:
• Whether the instruction passes its Condition code check.
• Whether the instruction is executed as part of exception entry.
• If EL2 is implemented, what HCR.{IMO, FMO, AMO} are set to.
• If EL3 is implemented, what SCR.{IRQ, FIQ, EA} are set to.

**Exception-trapping form**

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

• If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.

• If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that Table G2-25 shows. In the table, n/a means not applicable.

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>For exceptions taken to:</th>
<th>Other Secure PL1 modes</th>
<th>Non-secure PL1 modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>n/a</td>
<td>Secure Local exception vectors</td>
<td>Non-secure Local exception vectors</td>
</tr>
<tr>
<td>AArch32</td>
<td>Monitor exception vectors</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.
If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

G2.11.4 Usage constraints

See the following subsections:

• Usage constraints that apply to both forms of vector catch.
• Usage constraints that apply only to the address-matching form.

Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

• Vector catch is ignored, therefore a Vector Catch exception is not generated.
• Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

Note

The Exception level that debug exceptions are targeting is called the debug target Exception level, EL_D. Routing debug exceptions on page G2-5355 describes how EL_D is derived.

Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

• It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
• T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.

G2.11.5 Exception syndrome information and preferred return address for a Vector Catch exception

See the following:

• Exception syndrome information for a Vector Catch exception.
• Preferred return address for a Vector Catch exception on page G2-5411.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Vector Catch exception

The PE takes a Vector Catch exception as either:

• A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
• A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.
If the exception is taken to:

**PL1 Abort mode**

The PE sets all of the following:

- IFSR.FS to the code for a debug exception, 0b00010.
- DBGDSCRext.MOE to 0b0101, to indicate a Vector Catch exception.
- The IFAR with an UNKNOWN value.

**PL2 Hyp mode**

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See Table G2-26.
- Sets DBGDSCRext.MOE to 0b0101, to indicate a Vector Catch exception.
- Sets the HIFAR to an unknown value.

Note

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions* on page G2-5355.

**Preferred return address for a Vector Catch exception**

The preferred return address of a Vector Catch exception is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

### G2.11.6 Pseudocode description of Vector Catch exceptions

The `AArch32.VCRMatch()` pseudocode function checks whether the instruction at address generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The `AArch32.CheckVectorCatch()` pseudocode function uses `AArch32.VCRMatch()` to test whether the instruction generates a Vector Catch exception, and if `AArch32.VCRMatch()` returns TRUE it generates that event.

The `AArch32.Abort()` function processes the Fault record object returned by `AArch32.CheckVectorCatch()`, as described in *Abort exceptions on page G4-5454*. If there is a Vector Catch exception, the `AArch32.Abort()` function generates a Prefetch Abort exception.
G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a **Context synchronization event** has occurred.

For any instructions executed between the time when the change is made and the time when the next Context synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

**Example G2-3**

1. Software changes DBGDSCRext.MDBGen from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

**Example G2-4**

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

**Note**

Some register updates are self-synchronizing. Others require an explicit Context synchronization event. For more information, see:

- **Synchronization of changes to AArch32 System registers** on page G8-5632.
- **Accessing PSTATE fields** on page G1-5232.
- **Synchronization of changes to the external debug registers** on page H8-6538.

G2.12.1 State and mode changes without explicit context synchronization events

Most changes to the Exception level, and most changes to the Security state if EL3 is implemented, happen as a result of operations that are an explicit Context synchronization event. This is because taking an exception and returning from an exception are both explicit Context synchronization events, and the Privilege level and Security state can only change as a result of taking or returning from an exception.
However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit Context synchronization event. These are:

- AArch32 mode changes caused by MSR and CPS instructions. A mode change might be to a mode at a lower Privilege level.
- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.
Chapter G3
AArch32 Self-hosted Trace

This chapter describes the AArch32 self-hosted trace:

**Introductory information:**
- About self-hosted trace on page G3-5416.
- Trace Sinks on page G3-5416.
- Register controls to enable self-hosted trace on page G3-5416.

**Prohibited regions in trace:**
- Controls to prohibit trace at Exception levels on page G3-5417.
- Self-hosted trace and address translation on page G3-5417.

**Timestamps and Synchronization:**
- Self-hosted trace timestamps on page G3-5418.
- Synchronization in self-hosted trace on page G3-5419.
G3.1 About self-hosted trace

A PE Trace Unit generates trace data to describe the program flow of the PE.

The PE Trace Unit may be an implementation of a standard ARM Embedded Trace Macrocell (ETM), or another type of ARM Trace Architecture, or an IMPLEMENTATION DEFINED trace function.

If an ARMv8.4-compliant PE implements an ETM Architecture PE Trace Unit, ARMv8.4-Trace extension must be implemented.

If an ARMv8.4-compliant PE implements a Trace Unit that is not an ETM Architecture PE Trace Unit, ARM recommends that ARMv8.4-Trace extension is implemented, but this is not mandatory.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

If the self-hosted trace extensions are implemented, the PE Trace Unit must implement the system register interface. The PE Trace Unit and the PE must have the same view of the debug authentication interface. If ARMv8.4-Trace is implemented, ExternalNoninvasiveDebugEnabled() is always TRUE.

G3.1.1 Trace Sinks

The PE Trace Unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

ARM recommends that a system that includes ARMv8.4-Trace incorporates an ETR, and follows the system architecture described by the CoreSight Base System Architecture (CS-BSA).

The self-hosted trace extensions do not describe the programmers’ model trace sinks.

G3.1.2 Register controls to enable self-hosted trace

For EL1 using AArch64, see Chapter D3 AArch64 Self-hosted Trace.

If ARMv8.4-Trace is implemented, and external self-hosted trace is not implemented, self-hosted trace is always enabled.

If ARMv8.4-Trace is implemented, and external self-hosted trace is implemented, self-hosted trace is also enabled if one of the following is true:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, EL3 is implemented, SDCR.STE == 1 and ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- EDSCR.TFO == 1, EL3 is not implemented, the PE executes in Secure state and ExternalSecureNoninvasiveDebugEnabled() == FALSE.

The pseudocode function SelfHostedTraceEnabled() shows these rules.

If ARMv8.4-Trace is not implemented, SelfHostedTraceEnabled() returns FALSE.

While SelfHostedTraceEnabled() == FALSE, ExternalSecureNoninvasiveDebugEnabled() and ExternalNoninvasiveDebugEnabled() control whether external tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the PE Trace Unit external debug interface.
G3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception Level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited in Secure state when `SDCR.STE == 0`. If ARMv8.4-Trace is implemented but not enabled, tracing is prohibited in Secure state when `ExternalSecureNoninvasiveDebugEnabled() == FALSE`.

G3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled() == TRUE`, `TRFCR`, `TRFCR_EL1`, `TRFCR_EL2` and `HTRFCR` control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled() == FALSE`, these registers are ignored.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL0 if one of the following is true:
• The Effective value of `HCR_EL2.TGE == 0` and `TRFCR_EL2.E0TRE == 0`.
• The Effective value of `HCR.TGE == 0` and `TRFCR.E0TRE == 0`.
• The Effective value of `HCR_EL2.TGE == 1` and `TRFCR_EL1.E0HTRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL1 if `TRFCR.E1TRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL2 if `HTRFCR.E2TRE == 0`.

If `SelfHostedTraceEnabled() == TRUE`, tracing is prohibited at EL3 if one of the following is true:
• EL3 is in AArch64 state.
• EL3 is in AArch32 state and `TRFCR.E1TRE == 0`.

The pseudocode `TraceAllowed()` shows the above rules.

If `SelfHostedTraceEnabled() == TRUE`, Table G3-1 shows when export of PMU events Attributable to an Exception level is prohibited.

<table>
<thead>
<tr>
<th><code>HCR_EL2.TGE</code></th>
<th>Tracing prohibited in</th>
<th>Export of PMU events Attributable to this Exception level prohibited</th>

<td>EL3</td>
<td>EL3</td>
</tr>
</tbody>
</table>

G3.2.2 Self-hosted trace and address translation

A hypervisor can use `HTRFCR.CX` to control visibility of `VTTBR.VMID`.

If `SelfHostedTraceEnabled() == TRUE`, and `HTRFCR.CX == 0`, or if EL2 is not implemented:
• The value of `VTTBR.VMID` is not traced.
• Comparisons with `VTTBR.VMID` do not match and results of comparison are not exposed through the comparators.

The PE Trace Unit may either prohibit trace for these values, or may record a `VTTBR.VMID` value of zero in the trace.
G3.3 Self-hosted trace timestamps

For EL1 using AArch64, see Chapter D3 AArch64 Self-hosted Trace.

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While SelfHostedTraceEnabled() == FALSE, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When SelfHostedTraceEnabled() == TRUE, the trace time stamp is one of the following:

• The physical counter value CNTPCT_EL0 or CNTPCT.
• A virtual counter, which is calculated from the physical counter CNTPCT_EL0 minus an offset CNTVOFF_EL2, if EL2 is implemented and using AArch64.
• A virtual counter, which is calculated from the physical counter CNTPCT minus an offset CNTVOFF, if EL2 is implemented and using AArch32.
• If EL2 is not implemented, the value of the offset is zero.

The fields TRFCR_EL2.TS, TRFCR.TS and HTRFCR.TS control which counter is used for self-hosted trace.

The timestamp used for trace is shown in Table G3-2.

### Table G3-2 Timestamp used for trace.

<table>
<thead>

</tr>
<tr>
<td></td>
<td>0b11</td>
<td>xx</td>
<td>CNTPCT or CNTPCT_EL0</td>
</tr>
</tbody>
</table>

**Note**

The value of HCR_EL2.EL2 does not affect the counter used for the trace timestamp.
G3.4 Synchronization in self-hosted trace

The PE Trace Unit is an indirect observer of the trace control registers.

While `SelfHostedTraceEnabled() == TRUE`, indirect reads of the trace filter control fields, TRFCR.\{E1TRE, E0TRE\} and HTRFCR.\{E2TRE, E0HTRE\} are treated as indirect reads made by the instruction being traced, and are subject to the standard requirements for synchronization of System register accesses.

The `TSB CSYNC` operation is used to ensure that a trace operation, due to a PE Trace Unit generating trace for an instruction has completed. The `TSB CSYNC` operation may be reordered with respect to other instructions, so must be combined with at least one context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR or HTRFCR is guaranteed to be observed by the PE Trace Unit only after a subsequent Context synchronization event. For more information, see `Trace Synchronization Barrier (TSB CSYNC)` on page E2-3571.

While `SelfHostedTraceEnabled() == FALSE`, the PE Trace Unit might impose stronger synchronization requirements.
G3 AArch32 Self-hosted Trace
G3.4 Synchronization in self-hosted trace
Chapter G4
The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

• *About the memory system architecture* on page G4-5422.
• *Address space* on page G4-5423.
• *Mixed-endian support* on page G4-5424.
• *AArch32 cache and branch predictor support* on page G4-5425.
• *System register support for IMPLEMENTATION DEFINED memory features* on page G4-5448.
• *External aborts* on page G4-5449.
• *Memory barrier instructions* on page G4-5451.
• *Pseudocode description of general memory System instructions* on page G4-5452.
G4.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page E2-3575.

G4.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter G5 The AArch32 Virtual Memory System Architecture describes the AArch32 view of the VMSA.

G4.1.2 Memory attributes

Memory types and attributes on page E2-3586 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table G4-1 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Shareability</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(^a)</td>
<td>Outer Shareable</td>
<td>Non-cacheable.</td>
</tr>
<tr>
<td>Normal</td>
<td>One of:</td>
<td>One of:(^b):</td>
</tr>
<tr>
<td></td>
<td>• Non-shareable.</td>
<td>• Non-cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Inner Shareable.</td>
<td>• Write-Through Cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

\(^a\) Takes additional attributes, see Device memory on page E2-3590.
\(^b\) See also Cacheability, cache allocation hints, and cache transient hints on page G4-5428.

For more information on Cacheability and Shareability see The Cacheability and Shareability memory attributes on page E2-3576, Non-shareable Normal memory on page E2-3588, and Caches and memory hierarchy on page E2-3575.
G4.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see About VMSAv8-32 on page G5-5456.

G4.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

(address_of_current_instruction) + (size_of_executed_instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows 0xFFFF FFFF, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes 0xFFFFFFFF and 0x00000000, the bytes that apparently from 0x00000000 onwards come from an UNKNOWN address.

Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes 0xFFFFFFFF and 0x00000000, then the bytes that apparently come from 0x00000000 onwards come from UNKNOWN addresses.
### G4.3 Mixed-endian support

Table G4-2 shows the endianness of explicit data accesses and translation table walks.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTRL.EE</td>
</tr>
<tr>
<td>EL1</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTRL.EE</td>
</tr>
<tr>
<td>EL2</td>
<td>PSTATE.E</td>
<td>HSCTRL.EE</td>
<td>N/A</td>
</tr>
<tr>
<td>EL3</td>
<td>PSTATE.E</td>
<td>SCTLR(S).EE</td>
<td>N/A</td>
</tr>
</tbody>
</table>

AArch32 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR(S/NS).EE, HSCTRL.EE, and PSTATE.E are RW.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR(S/NS).EE and HSCTRL.EE are RES0. PSTATE.E is RW when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR(S/NS).EE and HSCTRL.EE are RES1. PSTATE.E is RW when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.

- All Exception levels support only little-endianness:
  - Each of SCTLR(S/NS).EE, HSCTRL.EE, PSTATE.E, and SPSR.E is RES0.

- All Exception levels support only big-endianness:
  - Each of SCTLR(S/NS).EE, HSCTRL.EE, PSTATE.E, and SPSR.E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

**Note**

- When using AArch32, ARM deprecates PSTATE.E having a different value from the equivalent System register EE bit when in EL1, EL2 or EL3. The use of the SETE0 instruction is also deprecated.

- If the higher Exception levels are using AArch64, the corresponding registers are:
  - SCTLR_EL1 for SCTLR(NS).
  - SCTLR_EL2 for HSCTRL.
  - SCTLR_EL3 for SCTLR(S).

The BigEndian() function determines whether the current Exception level and Execution state is using big-endian data.

For more information about endianness in the ARM architecture see *Endian support on page E2-3582*.
G4.4 AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:
• General behavior of the caches.
• Cache identification on page G4-5426.
• Cacheability, cache allocation hints, and cache transient hints on page G4-5428.
• Enabling and disabling the caching of memory accesses in AArch32 state on page G4-5429.
• Behavior of caches at reset on page G4-5431.
• AArch32 cache and branch predictor maintenance instructions on page G4-5435.
• About cache maintenance in AArch32 state on page G4-5431.
• AArch32 cache and branch predictor maintenance instructions on page G4-5435.
• Cache lockdown on page G4-5446.
• System level caches on page G4-5447.

See also Chapter G5 The AArch32 Virtual Memory System Architecture, and in particular Caches in VMSAv8-32 on page G5-5543.

——— Note ————
• Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.

• In the instruction mnemonics, MVA is a synonym for VA.

G4.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:
• The size, line length, and associativity of the cache.
• The cache allocation algorithm.
• Activity by other elements of the system that can access the memory.
• Speculative instruction fetching algorithms.
• Speculative data fetching algorithms.
• Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:
• A memory location present in the cache remains in the cache.
• A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

• The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  — A particular implementation.
  — Some memory attributes.

• An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

• A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
Note
For more information, see The interaction of cache lockdown with cache maintenance instructions on page G4-5446.

• Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

• It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.

• It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  — The translation regime at the current Exception level.
  — The translation regime at any higher Exception level.

• For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its Shareability domain.

• Any memory location is not guaranteed to remain incoherent with the rest of memory.

• The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR identifies the Cache Write-back Granule.

• The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

Note
The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR.{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

G4.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

• Affect the entire cache, for example ICIALLUIS.
• Operate by VA, for example ICIMVAU.
• Operate by set/way, for example DCISW.

The cache identification registers are:

• A single Cache Type Register, CTR, that defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

Note
It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches on page G4-5447.
A single Cache Level ID Register, CLIDR, that defines:

- The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
- The Level of Unification Inner Shareable (LoUIS), Level of Coherence (LoC) and the Level of Unification (LoU) for the caches. See Terms used in describing the cache maintenance instructions on page G4-5432 for a definition of these terms.
- An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.

A single Cache Size Selection Register, CSSEL, that selects the cache level and cache type of the current Cache Size Identification Register.

For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, that defines:

- Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
- The number of sets, associativity, and line length of the cache. See Terms used in describing the cache maintenance instructions on page G4-5432 for a definition of these terms.

Note

From ARMv8.3, it is possible to have multiple Cache Size Identification Registers. For more details, see Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     - An instruction cache.
     - A data or unified cache.
   - Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2

From ARMv8.3, two different formats are available for defining the number of sets and associativity of the currently selected cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions on page G4-5432.

When ARMv8.3-CCIDX is implemented:

- There are two Cache Size Identification Registers, CCSIDR and CCSIDR2.
- The length of the CCSIDR.Assoc field is 21 bits. This limits the associativity of the currently selected cache to $2^{21}$.
- The length of the CCSIDR2.NumSets field is 24 bits. This limits the number of sets in the currently selected cache to $2^{24}$.

This is the 64-bit format of the Cache Size Identification Register.
When ARMv8.3-CCIDX is not implemented:

- There is a single Cache Size Identification Register, CCSIDR.
- The length of the CCSIDR.Assoc field is 10 bits. This limits the associativity of the currently selected cache to $2^{10}$.
- The length of the CCSIDR.NumSets field is 15 bits. This limits the number of sets in the currently selected cache to $2^{15}$.

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

### G4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page E2-3586, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be used:

**For read accesses:** Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

**For write accesses:** Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

--- Note

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.

- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.

- For VMSAv8-32 translation table walks using the Long-descriptor translation table format, the appropriate TCR.[IRGNn, ORGNo] fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

---

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

**Transient cacheability hint**

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported for the VMSAv8-32 translation scheme when using the Long-descriptor translation table format. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.
Note

The architecture does not specify what is meant by a relatively short period.

When using the Short-descriptor translation table format, VMSA<8-32 cannot support the Transient hint.

The description of the MAIR0, MAIR1, HMAIR0, and HMAIR1 registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

G4.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

For the Non-secure PL1&0 translation regime

The Non-secure instance of SCTLR holds the EL1 controls that affect cacheability:

- When the value of SCTLR.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR2.CD is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 2 translation tables are Non-cacheable.
- When the value of HCR2.ID is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR.DC is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTLR.C. This applies to translations for both data and instruction accesses.

In addition, when the value of SCTLR.M is 0, indicating that the stage 1 translations are disabled for the translation regime, then if EL2 is using AArch32 and the value of HCR.DC is 0 or if EL2 is using AArch64 and the value of HCR_EL2.DC is 0, then:

- If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in Combining the Cacheability attribute on page G5-5523.
• The Non-secure SCTLR.\{C, I\} and HCR.DC fields have no effect on the Secure PL1&0 and EL2 translation regimes.
• The HCR2.\{ID, CD\} fields affect only stage 2 of the Non-secure PL1&0 translation regime.
• In Non-secure state, the PL1&0 translation regime can be described as the Non-secure EL1&0 translation regime. This is consistent with the equivalent AArch64 descriptions.

For the Secure PL1&0 translation regime

The Secure instance of SCTLR holds the controls that determine cacheability:

• When the value of SCTLR.C is 0:
  — All data accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.
  — All accesses to the Secure PL1&0 translation tables are Non-cacheable.
• When the value of SCTLR.I is 0:
  — All instruction accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.

In addition, when the value of SCTLR.M is 0, indicating that stage 1 translations are disabled, then:
• If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
• If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

The Secure SCTLR.\{I, C, M\} fields have no effect on the Non-secure PL1&0 and EL2 translation regimes.

For the EL2 translation regime

• When the value of HSCTLR.C is 0:
  — All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  — All accesses to the EL2 translation tables are Non-cacheable.
• When the value of HSCTLR.I is 0:
  — All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of HSCTLR.M is 0, indicating that stage 1 translations are disabled, then:
• If the value of HSCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
• If the value of HSCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

The HSCTLR.\{I, C, M\} fields have no effect on the PL1&0 and EL3 translation regimes.

The effect of the SCTLR.C or HSCTLR.C and HCR2.CD bits is reflected in the result of the address translation instructions in the PAR.

Note

The requirements in this section mean the architecturally required effects of SCTLR.I and HSCTLR.I are limited to their effects on caching instruction accesses in unified caches.
• This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in Mismatched memory attributes on page E2-3596 must be followed to manage the corresponding loss of coherency.

G4.4.5 Behavior of caches at reset

In ARMv8:

• All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.

• The Cacheability control fields described in Enabling and disabling the caching of memory accesses in AArch32 state on page G4-5429 reset to values that force all memory locations to be treated as Non-cacheable.

——— Note ————
This applies only to the controls that apply to the Translation regime that is used by the Exception level, PE mode, and Security state entered on reset.

• An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

• If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  — Provide a mechanism to ensure the correct initialization of the caches.
  — Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

• ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

Similar rules apply to:

• Branch predictor behavior, see Behavior of the branch predictors at reset on page G4-5439.

• TLB behavior, see TLB behavior at reset on page G5-5526.

G4.4.6 About cache maintenance in AArch32 state

The following sections give general information about cache maintenance in ARMv8:

• Terms used in describing the cache maintenance instructions on page G4-5432.

• The ARMv8 abstraction of the cache hierarchy on page G4-5434.

The following sections describe the AArch32 state cache maintenance instructions:

• AArch32 instruction cache maintenance instructions (IC*) on page G4-5436.

• AArch32 data cache maintenance instructions (DC*) on page G4-5437.

——— Note ————
Some descriptions of the cache maintenance instructions refer to the Cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR.{I, C} controls.
Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- Terminology for cache maintenance instructions operating by set/way.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

--- Note ---

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-5464.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

**Level**
The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR.

In the ARM architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy on page E2-3575.

**Set**
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

**Way**
The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

--- Note ---

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.
The *Clean and Invalidate* instructions address these two issues. The definitions of these instructions are:

**Clean** 
A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

**Invalidate** 
A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

--- **Note** ---
Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

--- **Clean and Invalidate** ---
A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

  **Point of Coherency (PoC)**
  The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

  --- **Note** ---
  The presence of system caches can affect the determination of the point of coherency as described in *System level caches* on page G4-5447.

  **Point of Unification (PoU)**
  The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.
  
  The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

  1. Clean data cache entry by address.
  2. Invalidate instruction cache entry by address.
The following fields in the CLIDR relate to these conceptual points:

**LoC, Level of Coherence**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level. If the LoUU field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**LoUIS, Level of Unification, Inner Shareable**
In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see the CLIDR description.

**The ARMv8 abstraction of the cache hierarchy**
The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- Cache maintenance instructions that operate by VA.
- Cache maintenance instructions that operate by set/way on page G4-5435.

**Cache maintenance instructions that operate by VA**
The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See Terms used in describing the cache maintenance instructions on page G4-5432 for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

AArch32 cache and branch predictor maintenance instructions on page G4-5435 lists the VA-based maintenance instructions.

The CTR holds minimum line length values for:

- The instruction caches.
- The data and unified caches.
These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

**Cache maintenance instructions that operate by set/way**

AArch32 cache and branch predictor maintenance instructions lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

### G4.4.7 AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table G4-3 shows the AArch32 System instructions. Instructions that take an argument include Rt in the instruction description.

AArch32 state also provides branch predictor maintenance instructions.

---

**Note**

- In Table G4-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.
- In AArch64 state, branch predictors are always invisible to software, and therefore AArch64 state does not provide any branch predictor maintenance instructions.

---

</table>
A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the BPIMVA, BPIALLIS, and BPIALL instructions can execute as NOPs.

The following subsections give more information about these instructions:
- AArch32 instruction cache maintenance instructions (IC*).
- AArch32 data cache maintenance instructions (DC*) on page G4-5437.
- Branch predictors on page G4-5437.
- General requirements for the scope of cache and branch predictor maintenance instructions on page G4-5439.
- Effects of instructions that operate by VA to the Point of Coherency on page G4-5439.
- Effects of instructions that operate by VA but not to the Point of Coherency on page G4-5440.
- Effects of All and set/way maintenance instructions on page G4-5440.
- Effects of virtualization and security on the AArch32 cache maintenance instructions on page G4-5441.
- Boundary conditions for cache maintenance instructions on page G4-5442.
- Ordering of cache and branch predictor maintenance instructions on page G4-5443.
- Performing cache maintenance instructions on page G4-5444.

**AArch32 instruction cache maintenance instructions (IC*)**

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:
- For an instruction executed at EL1, the current system ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or at EL1.
- For an instruction executed at EL1, the VMID.

That VA to PA translation might fault. However for an instruction cache maintenance instruction that operates by VA:
- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case on a Stage 2 fault on a stage 1 translation table walk.

For more information about the possible faults on an instruction that operates by VA, see *Types of MMU faults* on page G5-5547.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the completion requirements for cache and branch predictor maintenance instructions in *Completion and endpoint ordering* on page E2-3567.

Table G4-3 AArch32 System instructions for cache maintenance (continued)
See also *Ordering of cache and branch predictor maintenance instructions on page G4-5443.*

**AArch32 data cache maintenance instructions (DC*)**

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see *Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7206 or the instruction description.*

**DCISW** instructions executed at EL1 perform a clean and invalidate, meaning it performs the same maintenance as a **DCCISW** instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - EL2 is using AArch32 and the value of HCR.SWIO is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.SWIO is 1.

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from EL1.
- For an instruction executed from EL1, the VMID.

That VA to PA translation might fault. However a data or unified cache maintenance instruction that operates by VA cannot generate a Data Abort exception for a Domain fault, and cannot generate a Data Abort exception for a Permission fault, except for the Permission fault case on a Stage 2 fault on a stage 1 translation table walk.

For more information about the possible faults on an instruction that operates by VA, see *Types of MMU faults on page G5-5547.*

**DCIMVAC** and **DCISW** instructions executed at EL1 perform a clean and invalidate, meaning they perform the same maintenance as a **DCCIMVAC** or **DCCISW** instruction respectively, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- PL1&0 stage two address translation is enabled, meaning either:
  - EL2 is using AArch32 and the value of HCR.VM is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VM is 1.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also *Ordering of cache and branch predictor maintenance instructions on page G4-5443.*

**Branch predictors**

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see *Specific requirements for branch predictor maintenance instructions on page G4-5438.*

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as NOPs.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.
Note

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also Ordering of cache and branch predictor maintenance instructions on page G4-5443.

Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.
- For the Non-secure PL1&0 translation regime:
  - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
  - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
  - Enabling or disabling stage 2 translations.
- Writing new mappings to the translation tables.
- Any change to the TTBR0, TTBR1, or TTBCR registers, unless:
  - For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
  - For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.
- Any change to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

Note

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an MMU fault.
- Changing a translation that generates an MMU fault to a valid translation.

Failure to invalidate entries might give CONSTRAINED UNPREDICTABLE results, caused by the execution of old branches. For more information, see Ordering of cache and branch predictor maintenance instructions on page G4-5443.

Note

In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:

- Changing the ContextID or VMID.
— A cache maintenance instruction that is identified as also flushing the branch predictors, see AArch32 cache and branch predictor maintenance instructions on page G4-5435.

Cache maintenance system instructions on page K13-7440 shows the branch predictor maintenance operations in a VMSA implementation.

**Behavior of the branch predictors at reset**

In AArch32 state:

- If branch predictors are not architecturally invisible:
  - The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
  - The branch predictors are disabled at reset.

- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.

- ARM recommends that whenever an invalidation routine is required, it is based on the AArch32 branch predictor maintenance operations.

Similar rules apply:

- To cache behavior, see Behavior of caches at reset on page G4-5431.
- To TLB behavior, see TLB behavior at reset on page G5-5526.

**General requirements for the scope of cache and branch predictor maintenance instructions**

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page G4-5425, Behavior of caches at reset on page G4-5431, and Preloading caches on page E2-3578.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

—— Note ———

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

**Effects of instructions that operate by VA to the Point of Coherency**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.
In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

**Table G4-4 PEs affected by cache maintenance instructions to the Point of Coherency**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA but not to the Point of Coherency**

The following instructions operate by VA but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, **DCCMVAU**.
- Invalidate instruction cache line by MVA to Point of Unification, **ICIMVAU**.
- Invalidate by MVA from branch predictors, **BPIMVA**.

For these instructions, **Table G4-5** shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table G4-5 PEs affected by cache maintenance instructions to the Point of Unification**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable or Outer Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>

</tbody>
</table>

**Note**

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.

**Effects of All and set/way maintenance instructions**

The **ICIALLU**, **BPIALL** and `BC` set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, **ICIALLU** also performs a **BPIALL** operation.

The **ICIALLUIS** and **BPIALLIS** instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, **ICIALLUIS** also performs a **BPIALLIS** operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

**Note**

The possible presence of system caches, as described in [System level caches](#) on page G4-5447, means architecture does not guarantee that all levels of cache can be maintained using set/way instructions.
Effects of virtualization and security on the AArch32 cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table G4-6 shows the effects of virtualization and security on these maintenance instructions.

**Table G4-6 Effects of virtualization and security on the AArch32 cache maintenance instructions**

<table>
<thead>

</table>
| Invalidate, Clean, or Clean and Invalidate by VA: DCIMVAC, DCCMVAC, DCCMVAU, DCCIMVAC | Either | All lines that hold the PA that, in the current translation regime, are mapped to by the combination of all of:
- The specified VA.
- For an instruction executed at EL1, the current ASID if the location is mapped to by a non-global page.
- For an instruction executed at EL1, the current VMID. |
| Invalidate, Clean, or Clean and Invalidate by set/way: DCISW, DCCSW, DCCISW | Non-secure | Line specified by set/way provided that the entry comes from the Non-secure PA space. |
| | Secure | Line specified by set/way regardless of the PA space that the entry has come from. |
| Instruction cache maintenance instructions | | |
| Invalidate by VA: ICIMVACAU | Either | All lines corresponding to the specified VA\(^b\) in the current translation regime and:
- For an instruction executed at EL1 or EL0, the current ASID. |
| | | For an instruction executed at EL1 or EL0, the current VMID. |
| Invalidate All: ICIALLU, ICIALLUIS | | Can invalidate any unlocked entry in the instruction cache. |
| | | Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information: |
| | | **Non-secure** |
| | | An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID. \(^a\) |
| | | An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state. |
| | | **Secure** |
| | | The instruction must invalidate all instruction cache lines. |
| Branch predictor instructions\(^c\) | | |
| Invalidate by VA: BPIMVA | Either | All lines that, in the current translation regime, are mapped to by the combination of:
- The specified VA. |
| | | For an instruction executed at EL1 or EL0, the current ASID if the location is mapped to by a non-global page. |
| | | For an instruction executed at EL1 or EL0, the current VMID. |
| Invalidate all: BPIALL, BPIALLIS | | Can invalidate any unlocked entry in the branch predictor. |
| | | Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information. |
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in \textit{The interaction of cache lockdown with cache maintenance instructions} on page G4-546 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way instructions can, instead, perform a clean and invalidate by set/way.

- The AArch32 Data cache invalidate instructions DCIMVAC and DCISW, perform a cache clean as well as a cache invalidate, meaning DCIMVAC performs the same invalidation as a DCCIMVAC instruction, and DCISW performs the same invalidation as a DCCISW instruction, if both of the following apply:
  - The value of HCR.VM is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

- The AArch32 Data cache invalidate by set/way instruction DCISW performs a cache clean as well as a cache invalidate, meaning it performs the same invalidation as a DCCISW instruction, if both of the following apply:
  - The value of HCR.SWIO is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

- When the value of HCR.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the TLBIMVA, TLBIMVA2, TLBIMVAL, TLBIMVALA, and ICIALLU instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example ICIALLU performs the invalidation that would be performed by ICIALLUIS, and BPIALL performs the invalidation that would be performed by BPIALLIS.

For more information about the cache maintenance instructions, see \textit{About cache maintenance in AArch32 state} on page G4-543, \textit{AArch32 cache and branch predictor maintenance instructions} on page G4-5435, and Chapter G5 \textit{The AArch32 Virtual Memory System Architecture}.

\textbf{Boundary conditions for cache maintenance instructions}

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
• Any applicable domain control of the address accessed.
• The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

### Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.
  - All cache and branch predictor instructions that specify an address:
    - Execute in program order relative to all cache and branch predictor operations that do not specify an address.
    - Execute in program order relative to all cache and branch predictor operations that specify the same address.
    - Can execute in any order relative to cache and branch predictor operations that specify a different address.

- Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.

- Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in Ordering and completion of TLB maintenance instructions on page G5-5532 before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.

- A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.
  - Also, a DMB instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the DMB are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.

- A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.

- A Context synchronization event is required to guarantee the effects of any branch predictor maintenance operation. This means a Context synchronization event causes the effect of all completed branch predictor maintenance operations appearing in program order before the Context synchronization event to be visible to all instructions after the Context synchronization event.
  - This means that, if a branch instruction appears after an invalidate branch predictor operation and before any Context synchronization event, it is CONstrained UNpredictable whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONstrained UNpredictable behavior.

- Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see Definition of the ARMv8 memory model on page E2-3562.
  - Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.
• There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

• There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

• Software must execute a Context synchronization event after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

A DSB or DMB instruction intended to ensure the completion of cache maintenance instructions or branch predictor instructions must have an access type of both loads and stores.

See also the completion requirements for cache and branch predictor maintenance instructions in Completion and endpoint ordering on page E2-3567.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see Instruction caches on page G5-5543.

Example G4-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCMVAVU Rn ; Clean data cache by MVA to point of unification (PoU)
DSB ; Ensure visibility of the data cleaned from cache
ICIMVAV U Rn ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn ; Invalidate branch predictor by MVA to PoU
DSB ; Ensure completion of the invalidations
ISB ; Synchronize the fetched instruction stream

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

• For data or unified cache maintenance, uses the CTR.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.

• For instruction cache maintenance, uses the CTR.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is
not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

*System level caches on page G4-5447* refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes the current Cache Size Identification Register is in 32-bit format. For more information, see *Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2 on page G4-5427.*

```
MRC p15, 1, R0, c0, c0, 1   ; Read CLIDR into R0

CMP R3, R10
DSB                         ; ensure completion of previous cache maintenance instruction
BGT Loop1
Finished
```

Similar approaches can be used for all cache maintenance instructions.
G4.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DCCSW.
  - Cache invalidate by set/way, DCISW.
  - Cache clean and invalidate by set/way, DCISW.
  - Instruction cache invalidate all, ICIALLU and ICIALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See Data Abort exception on page G1-5285.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DCCMVAC and DCCMVAU.
- Cache invalidate by virtual address, DCIMVAC.
- Cache clean and invalidate by virtual address, DCCIMVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See DFSR or HSR.

In an implementation that includes EL2, if HCR.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.
Note

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space.

G4.4.9 System level caches

The ARM Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR, CCSIDR2, and CLIDR, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.
G4.5 System register support for IMPLEMENTATION DEFINED memory features

The VMSAv8-32 defines the following registers for describing IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, tcmtr must be implemented on any implementation where EL1 or above supports AArch32. The format of this register is IMPLEMENTATION DEFINED.

- The System register encoding space with \{<\text{coproc}==0b1111, \text{CRn}==c9, \text{CRm}==\{c0-c2, c5-c7}\}\} is IMPLEMENTATION DEFINED for all values of \text{opc2} and \text{opc1}. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.

- In a VMSAv8-32 implementation, part of the System register encoding space with \{<\text{coproc}==0b1111, \\text{CRn}==c10}\} is IMPLEMENTATION DEFINED and reserved for TLB functionality, see TLB lockdown on page G5-5527.

- The System register encoding space with \{<\text{coproc}==0b1111, \text{CRn}==c11, \text{CRm}==\{c0-c8, c15\}\}\} is IMPLEMENTATION DEFINED for all values of \text{opc2} and \text{opc1}. This space is reserved for DMA operations to and from the TCMs.

In addition, the System register encoding space with \{<\text{coproc}==0b1111, \text{CRn}==c15}\} is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G7-5610.
G4.6 External aborts

The ARM architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of:
• Synchronous.
• Precise asynchronous.
• Imprecise asynchronous.

For more information, see Exception terminology on page G1-5210.

The RAS Extension provides an expanded taxonomy for describing aborts. When the RAS Extension is not implemented, the ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

VMSAv8-32 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the External abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported. Asynchronous External aborts generate SError interrupt exceptions.

In AArch32 state:
• SError interrupts are taken as asynchronous Data Abort exceptions.
• Synchronous External aborts:
  — On data accesses are taken as synchronous Data Abort exceptions.
  — On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

See also:
• External abort on a translation table walk on page G5-5554.
• Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running. ARM recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:
• Provision for classification of External aborts.
• Parity or ECC error reporting, RAS Extension not implemented on page G4-5450.

The section Exception reporting in a VMSAv8-32 implementation on page G5-5558 describes the reporting of External aborts.

G4.6.1 Provision for classification of External aborts

For an External abort taken to a privileged mode other than Hyp mode, an implementation can use the DFSR.ExT or IFSR.ExT bits to provide more information about the External abort:
• DFSR.ExT provides an IMPLEMENTATION DEFINED classification of External aborts on data accesses.
• IFSR.ExT provides an IMPLEMENTATION DEFINED classification of External aborts on instruction accesses.

For an External abort taken to Hyp mode, the HSR.EA bit, provides an IMPLEMENTATION DEFINED classification of External aborts.

For all aborts other than External aborts these bits return a value of 0.
If the RAS Extension is implemented:

- The HSR.AET field provides information about the state of the PE following an SError interrupt exception taken to Hyp mode.
- The DFSR.AET field provides information about the state of the PE following an asynchronous Data Abort exception.
- The implementation might define error record registers.

For more information on the RAS Extension, see ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

### G4.6.2 Parity or ECC error reporting, RAS Extension not implemented

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Exception reporting in a VMSAv8-32 implementation on page G5-5558. However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
G4.7 Memory barrier instructions

Memory barriers on page E2-3568 describes the memory barrier instructions. This section describes the system level controls of those instructions.

G4.7.1 EL2 control of the Shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports Shareability limitations on the data barrier instructions, the HCR.BSU field can modify the required Shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table G4-7 shows the encoding of this field:

<table>
<thead>
<tr>
<th>HCR.BSU</th>
<th>Minimum Shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, Shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1 in Non-secure state, Table G4-8 shows how the HCR.BSU is combined with the Shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

<table>
<thead>
<tr>
<th>Shareability specified by the DMB or DSB argument</th>
<th>HCR.BSU</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full system</td>
<td>Any</td>
<td>Full system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>00, 01, or 10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td></td>
<td>11, Full system</td>
<td>Full system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>00 or 01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td></td>
<td>10, Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td></td>
<td>11, Full system</td>
<td>Full system</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>00, No effect</td>
<td>Non-shareable</td>
</tr>
<tr>

<td>10, Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td></td>
<td>11, Full system</td>
<td>Full system</td>
</tr>
</tbody>
</table>
G4.8 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access.
- Unaligned memory access on page G4-5453.
- Exclusives monitors operations on page G4-5453.
- Access permission checking on page G4-5454.
- Abort exceptions on page G4-5454.
- Memory barriers on page G4-5454.

G4.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, MemHint_RA, and MemHint_RW_A constants.
- Access permissions, defined by the Permissions type.

G4.8.2 Basic memory access

The two forms of the _Mem[] accessor, non-assignment (memory read) _Mem[] and assignment (memory write) _Mem[], are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using desc.paddress, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in desc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page E2-3586, Definition of the ARMv8 memory model on page E2-3562, and Atomicity in the ARM architecture on page E2-3558.

An additional parameter to the _Mem[] accessor defines the access type, for example normal, exclusive, or ordered, and whether the access is made as part of a translation table walk.

The actual implemented array of memory might be smaller than the maximum address size that can be accessed from AArch32 state. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to External aborts or SErrors (System Errors).

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

--- Note ---

A stage of address translation using VMSAv8-32 cannot generate an output address of more than 40 bits.

G4.8.3 Aligned memory access

The AArch32_MemSingle[] functions make atomic, little-endian accesses of size bytes.
### G4.8.4 Unaligned memory access

See Unaligned data access on page E2-3580 for details of the SCTLR.A and HSCTLR.A controls on the generation of alignment faults. The HSCTLR control applies to Normal memory accesses from Hyp mode, and the SCTLR control applies to Normal memory accesses from all other modes.

The Mem_with_type[] functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to AArch32.MemSingle[]. If that access is not aligned but passes the AArch32.CheckAlignment() checks, each form of the function synthesizes the required access from multiple calls to AArch32.MemSingle[]. It also reverses the byte order if the access is big-endian.

### G4.8.5 Exclusives monitors operations

The AArch32.SetExclusiveMonitors() function sets the Exclusives monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by size, at the VA address. The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors and therefore completes successfully.

The AArch32.ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors, by checking whether the Exclusives monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch32.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress.paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is
IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

**G4.8.6 Access permission checking**

The function AArch32.CheckPermission() is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in Memory access control on page G5-5502.

**G4.8.7 Abort exceptions**

The function AArch32.Abort() generates a Data Abort exception or a Prefetch Abort exception by calling the AArch32.TakeDataAbortException() or AArch32.TakePrefetchAbortException() function.

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode description of VMSAv8-32 memory system operations on page G5-5584 provides a number of wrappers to generate a FaultRecord.

The function AArch32.NoFault() returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

**G4.8.8 Memory barriers**

The definition for the memory barrier functions is given by the enumerations MBReqDomain and MBReqTypes.

These enumerations define the required Shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures DataMemoryBarrier(), DataSynchronizationBarrier(), and InstructionSynchronizationBarrier() perform the memory barriers.
Chapter G5
The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following sections:

- About VMSAv8-32
- The effects of disabling address translation stages on VMSAv8-32 behavior
- Translation tables
- The VMSAv8-32 Short-descriptor translation table format
- The VMSAv8-32 Long-descriptor translation table format
- Memory access control
- Memory region attributes
- Translation Lookaside Buffers (TLBs)
- TLB maintenance requirements
- Caches in VMSAv8-32
- VMSAv8-32 memory aborts
- Exception reporting in a VMSAv8-32 implementation
- Address translation instructions
- Pseudocode description of VMSAv8-32 memory system operations
- About the System registers for VMSAv8-32
- Functional grouping of VMSAv8-32 System registers

Note
This chapter must be read with Chapter G4 The AArch32 System Level Memory Model.
G5.1 About VMSAv8-32

This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extensions, the Large Physical Address Extension, and the Virtualization Extensions.

This chapter describes the control of the VMSA by Exception levels that are using AArch32. Security state, Exception levels, and AArch32 execution privilege on page G1-5218 summarizes how the AArch32 PE modes map onto the Exception levels.

ARMv8.4-SecEL2, if implemented, is not available in AArch32 state and EL2 only executes in Non-secure state.

ARMv8.4-S2FWB, if implemented, is not available in AArch32 state. If EL2 is executing in AArch64 state 2 stage translations might be affected. For more informations see Chapter D5 The AArch64 Virtual Memory System Architecture.

Chapter D5 The AArch64 Virtual Memory System Architecture describes the control of the VMSA by Exception levels that are using AArch64.

For details of the VMSA differences in previous versions of the ARM architecture, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a stage of address translation.

In VMSAv8-32, the Memory Management Unit (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

**For operation in Secure state**

A single stage of address translation, for use when executing at PL1 or EL0. This is the Secure PL1&0 stage 1 address translation stage.

**For operation in Non-secure state**

- A single stage of address translation for use when executing at EL2. This is the Non-secure EL2 stage 1 address translation stage.
- Two stages of address translation for use when executing at PL1 or EL0. These are:
  - The Non-secure PL1&0 stage 1 address translation stage.
  - The Non-secure PL1&0 stage 2 address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

However, if the PE is executing at EL0 using AArch32 when EL1 is using AArch64 then it is using the VMSAv8-64 EL1&0 translation regime, described in Chapter D5 The AArch64 Virtual Memory System Architecture.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called translation tables.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see About address translation for VMSAv8-32 on page G5-5459.

The translation tables define the following properties:

**Access to the Secure or Non-secure address map**

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.
Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.
- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes

These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
  - Device-nGnRnE
  - Device-nGnRE

- The Long-descriptor translation table format supports, in addition, the following Device memory types:
  - Device-nGRE
  - Device-GRE

Note

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see Memory types and attributes on page E2-3586.

Address translation mappings

An address translation maps an input address to an output address.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a virtual address (VA), as the input address, and translates it to a different output address:

- If only one stage of translation is provided, this output address is the physical address (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an intermediate physical address (IPA).

Note

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible Security states and privilege levels of memory accesses define a set of translation regimes, where a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. See The VMSAv8-32 translation regimes on page G5-5458.

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see Functional grouping of VMSAv8-32 System registers on page G5-5591.
The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

- The VMSAv8-32 translation regimes.
- Address types used in a VMSAv8-32 description on page G5-5459.
- Address spaces in VMSAv8-32 on page G5-5459.
- About address translation for VMSAv8-32 on page G5-5459.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in Organization of the remainder of this chapter on page G5-5462.

### G5.1.1 The VMSAv8-32 translation regimes

As introduced in Address translation mappings on page G5-5457, a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. Figure G5-1 shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

![Figure G5-1 VMSAv8-32 translation regimes, and associated control](image)

**Note**

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

*Limited use of Privilege level in ARMv8 AArch32 state on page G1-5219* describes the mapping between the PE modes and the Privilege levels (PLs).

**Alternative descriptions of the PL1&0 translation regime**

The PL1&0 is described in terms of Privilege level because of the way the AArch32 PE modes map onto the Exception levels, as described in Limited use of Privilege level in ARMv8 AArch32 state on page G1-5219. The description of this translation regime in terms of the Exception levels using depends on the current state of the PE, as follows:

- In Non-secure state, PL1 always maps to EL1, and therefore the Non-secure PL1&0 translation regime could be described as the Non-secure EL1&0 translation regime.

- In Secure state:
  - When EL3 is using AArch32, PL1 maps to EL3, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL3&0 translation regime,
  - When EL3 is using AArch64, Secure PL1 maps to Secure EL1, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL1&0 translation regime,

However, these descriptions all refer to the same translation regime, with the same System registers associated with its stage 1 translations. Therefore, the regime is generally referred to as the PL1&0 translation regime.

**Note**

As Figure G5-1 shows, stage 2 translation is supported only in Non-secure state.
G5.1.2 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

--- Note ---

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

Virtual address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of `0x00000000-0xFFFFFFFF`.

Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

Physical address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G5.1.3 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

--- Note ---

AArch32 defines two translation table formats. The Long-descriptor format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The Short-descriptor format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

G5.1.4 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A translation table defines the mapping from one address type to another, and a Translation table base register (TTBR) indicates the start of a translation table. Each implemented stage of address translation shown in Figure G5-1 on page G5-5458 requires its own translation tables.
For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

**VMSAv8-32 without EL2 or EL3**

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by TTBR0 and TTBR1, and controlled by TTBCR.

**VMSAv8-32 with EL3 but without EL2**

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each Security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of TTBR0 and TTBR1, and controlled by the Secure and Non-secure copies of TTBCR.

**VMSAv8-32 with EL2 but without EL3**

The implementation supports the following stages of address translation:

- **Non-secure EL2 stage 1 address translation**
  The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

- **Non-secure PL1&0 stage 1 address translation**
  Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

- **Non-secure PL1&0 stage 2 address translation**
  The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

**VMSAv8-32 with EL2 and EL3**

The implementation supports all of the stages of address translation, as follows:

- **Secure PL1&0 stage 1 address translation**
  Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of TTBR0 and TTBR1, and controlled by the Secure instance of TTBCR.

- **Non-secure EL2 stage 1 address translation**
  The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

- **Non-secure PL1&0 stage 1 address translation**
  Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

- **Non-secure PL1&0 stage 2 address translation**
  The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

Figure G5-2 on page G5-5461 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32.
The term *Typically configured* is used in Figure G5-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G5-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.

- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple stages of address translation, as Figure G5-2 shows.
- A single stage of address translation takes an input address and translates it to an output address.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The attributes and access permissions of the addressed memory.

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.
Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure PL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure PL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
  - MAIR0, MAIR1, AMAIR0, and AMAIR1.
  - TTBR0, TTBR1, TTBCR, TTBCR2, and CONTEXTIDR.
  - SCTLR.
- The registers associated with the stage 2 translations:
  - VTTBR and VTCR.
  - HSCTLR.

Note

Only some fields of SCTLR affect the stage 1 translation, and only some fields of HSCTLR affect the stage 2 translation. However, in each case, changing these fields requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure PL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure PL1&0 translation regime for speculative memory accesses.

When entering an Exception level on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered, will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

Note

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

G5.1.5 Organization of the remainder of this chapter

The remainder of this chapter is organized as follows.
The next part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G5-5464.
- *Translation tables* on page G5-5468.
- *Secure and Non-secure address spaces* on page G5-5471.
- *The VMSAv8-32 Short-descriptor translation table format* on page G5-5473.
- *The VMSAv8-32 Long-descriptor translation table format* on page G5-5482.
- *Memory access control* on page G5-5502.
- *Memory region attributes* on page G5-5513.
- *Translation Lookaside Buffers (TLBs)* on page G5-5525.
- *TLB maintenance requirements* on page G5-5529.

*Caches in VMSAv8-32* on page G5-5543 describes VMSAv8-32-specific cache requirements.

The following sections then describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

- *VMSAv8-32 memory aborts* on page G5-5546.
- *Exception reporting in a VMSAv8-32 implementation* on page G5-5558.

*Address translation instructions* on page G5-5577 then describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the primary encoding spaces, (coproc==0b1110) and (coproc==0b1111) for these registers:

- *About the System registers for VMSAv8-32* on page G5-5586.

**Note**

The System registers in the (coproc==0b1110) encoding space provide the following functionality:

- Self-hosted debug. These registers are described in *Debug registers* on page G8-6130.
- The System register interface to a PE Trace Unit These registers are not described in this manual.
- Jazelle registers. These registers are summarized in *Legacy feature registers and system instructions* on page K13-7442.

Therefore, there is no summary of these registers by functional groups.

*Pseudocode description of VMSAv8-32 memory system operations* on page G5-5584 then summarizes the pseudocode functions that describe many features of VMSAv8-32 operation.
### G5.2 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G5-5456 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- **SCTLR.M**, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- **SCTLR.M**, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- **HCR.VM** controls Non-secure PL1&0 stage 2 address translation.
- **HSCTLR.M** controls Non-secure EL2 stage 1 address translation.

**Note**

The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:

- Is controlled by the HCR if EL2 is using AArch32.
- Is controlled by the HCR_EL2 if EL2 is using AArch64.

For this reason, links to the HCR link to a table that disambiguates between the AArch32 HCR and the AArch64 HCR_EL2.

- If EL2 is using AArch64, then the equivalent of the Non-secure EL2 translation regime is described in Chapter D5 The AArch64 Virtual Memory System Architecture, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- **VMSAv8-32 behavior when stage 1 address translation is disabled**
- **VMSAv8-32 behavior when stage 2 address translation is disabled** on page G5-5466.
- **Behavior of instruction fetches when all associated address translations are disabled** on page G5-5466.

Enabling stages of address translation on page G5-5466 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

### G5.2.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

#### Non-secure PL1 and EL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or EL0 mode when HCR.DC is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

See also Effect of the HCR.DC field on page G5-5465.

#### All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

**Data access**

The stage 1 translation assigns the Device-nGnRnE memory type.

**Instruction access**

The stage 1 translation assigns Normal memory attribute, with the Cacheability and Shareability attributes determined by the value of:

- The Secure instance of SCTLR.I for the Secure PL1&0 translation regime.
- The Non-secure instance of SCTLR.I for the Non-secure PL1&0 translation regime.
- HSCTLR.I for the Non-secure EL2 translation regime.
In these cases, the meaning of the I field is as follows:

**When I is set to 0**
- The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

**When I is set to 1**
- The stage 1 translation assigns the attributes Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

--- **Note**

On some implementations, if the SCTLR.TRE field is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when SCTLR.TRE is set to 0 are IMPLEMENTATION DEFINED, see SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers on page G5-5518.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

--- **Note**

Alignment checking is performed, and therefore Alignment faults can occur.

---

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or EL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also [Behavior of instruction fetches when all associated address translations are disabled](#) on page G5-5466.

### Effect of the HCR.DC field

The **HCR.DC** field determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or EL0 mode with **HCR.DC** set to 1:
- For all purposes other than reading the value of the **SCTLR**, the PE behaves as if the value of the **SCTLR.M** field is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the **HCR**, the PE behaves as if the value of the **HCR.VM** field is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of **HCR.DC** might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the **HCR.DC** value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values](#) on page K1-7199.

### Effect of disabling translation on maintenance and address translation instructions

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any **ATS1C** or **ATS12NSO** address translation instruction that accesses the Non-secure state translation reflects the effect of the **HCR.DC** field.
G5.2.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see Behavior of instruction fetches when all associated address translations are disabled.

G5.2.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:

- From Secure PL1 and EL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure EL2 stage 1 address translation is disabled
- From Non-secure PL1 and EL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - HCR.DC is set to 0.

In these cases, when execution is in AArch32 state a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same 4KB block of memory, aligned to 4KB, as an instruction which a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset, or is in the 4KB block immediately following such a block.

- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - If the branch predictor is architecturally invisible, the last synchronization of instruction cache maintenance targeting the address of the branch instruction.
  - If the branch predictor is not architecturally invisible, the last synchronization of branch predictor maintenance targeting the address of the branch instruction.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

--- Note ---

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.

- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

G5.2.4 Enabling stages of address translation

On powerup or reset, only the SCTLR.M field for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other SCTLR.M and HSCTLR.M fields that are implemented are UNKNOWN after the reset.
This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, SCTLR.M, is banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the SCTLR.M field resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of SCTLR.M is UNKNOWN.

- On an implementation that includes EL2, where EL2 is using AArch32, the HSCTLR.M field, that controls the Non-secure EL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.

- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by SCTLR.M, that resets to 0.

**Note**

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the System registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.
G5.3 Translation tables

VMSAv8-32 defines two alternative translation table formats:

**Short-descriptor format**

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

**Long-descriptor format**

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

--- Note ---
- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its translation granule. This can be 4KB, 16KB, or 64KB. See *The VMSAv8-64 translation table format* on page G5-5468.

In all implementations, of the possible address translations shown in *Figure G5-2 on page G5-5461*, for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the TTBCR.EAE field indicates the current translation table format.
- The translation tables for the Non-secure EL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- *The VMSAv8-32 Short-descriptor translation table format* on page G5-5473.
- *The VMSAv8-32 Long-descriptor translation table format* on page G5-5482.

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- *Translation table walks for memory accesses using VMSAv8-32 translation regimes* on page G5-5469.
- *Information returned by a translation table lookup* on page G5-5469.
- *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G5-5470.
- *Control of translation table walks on a TLB miss* on page G5-5471.
- *Access to the Secure or Non-secure PA map* on page G5-5471.

See also *TLB maintenance requirements* on page G5-5529.
G5.3.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G5-5479.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-5497.

Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1 lookup. However, with the Long-descriptor translation table format, the starting-level can be either a level 1 or a level 2 lookup.

For the PL1&0 stage 1 translations, SCTLR.EE determines the endianness of the translation table lookups. SCTLR is banked, and therefore the endianness is determined independently for each Security state.

HSCTLR.EE defines the endianness for the Non-secure EL2 stage 1 and Non-secure PL1&0 stage 2 translations.

Note

Dynamically changing translation table endianness

Because any change to SCTLR.EE or HSCTLR.EE requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- SCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by SCTLR.EE.
  - Executing with SCTLR.M set to 0.
- HSCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by HSCTLR.EE.
  - Executing with HSCTLR.M set to 0.

The PA of the base of the starting-level translation table is determined from the appropriate TTBR, see Determining the translation table base address in the VMSAv8-32 translation regimes on page G5-5470.

For more information, see Ordering and completion of TLB maintenance instructions on page G5-5532.

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the Shareability attributes described in the TTBR. These Shareability attributes must be consistent with the Shareability attributes for the translation tables themselves.

G5.3.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing address map control, access controls, or region attributes. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in Access to the Secure or Non-secure PA map on page G5-5471.

Memory accesses from Non-secure state can only access the Non-secure address map.
**Access controls**

Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, an MMU fault is generated and there is no memory access.

*Memory access control on page G5-5502* describes the properties in this group.

**Attributes**

Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

*Memory region attributes on page G5-5513* describes the properties in this group.

---

### G5.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As Figure G5-2 on page G5-5461 shows:

- For a Non-secure EL2 stage 1 translation, the HTTBR holds the required base address. The HTCR is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the VTTBR holds the required base address. The VTCR is the control register for these translations.
- For a PL1&0 stage 1 translation, either TTBR0 or TTBR1 holds the required base address. The TTBCR is the control register for these translations.

The Non-secure copies of TTBR0, TTBR1, and TTBCR, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of TTBR0, TTBR1, and TTBCR, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- TTBR0 can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If TTBR0 is configured to describe the translation of VAs in the lower part of the address map, TTBR1 is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the TTBCR determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G5-5478.*
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G5-5491.*

Example G5-1 shows a typical use of the two sets of translation tables:

---

**Example G5-1 Example use of TTBR0 and TTBR1**

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

**TTBR0**  
Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0 is updated to point to the level 1 translation table for the new context.
- TTBCR is updated if this change changes the size of the translation table.
- The CONTEXTIDR is updated.

TTBCR can be programmed so that all translations use TTBR0 in a manner compatible with architecture versions before ARMv6.

**TTBR1**  
Used for operating system and I/O addresses, that do not change on a context switch.
G5.3.4 Control of translation table walks on a TLB miss

Two fields in the TCR for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two fields are the:

- PD0 and PD1 fields, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 fields, on a PE using the Long-descriptor translation table format.

Note

For the VMSAv8-32 translation regimes, the different field names are because the fields are in different positions in TTBCR, depending on the translation table format.

The effect of these fields is:

(E)PDx == 0  If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current Security state determines whether the memory access is Secure or Non-secure.

(E)PDx == 1  If a TLB miss occurs based on TTBRx, a level 1 Translation fault is returned, and no translation table walk is performed.

G5.3.5 Access to the Secure or Non-secure PA map

As stated in Address spaces in VMSAv8-32 on page G5-5459, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure TTBR0 and TTBR1. In both translation table formats in the Secure translation tables, the NS field in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

NS == 0  Access the Secure PA space.

NS == 1  Access the Non-secure PA space.

Note

In the Non-secure translation tables, the corresponding field is SBZ. Non-secure accesses always access the Non-secure PA space, regardless of the value of this field.

The Long-descriptor translation table format extends this control, adding an NSTable field to the Secure translation tables, as described in Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G5-5490. In the Non-secure translation tables, the corresponding field is SBZ, and Non-secure accesses ignore the value of this field.

The following sections describe the address map controls in the two implementations:

- Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-5478.
- Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-5490.

The following subsection gives more information.

Secure and Non-secure address spaces

EL3 provides two PA spaces, a Secure PA space and a Non-secure PA space.

As described in Access to the Secure or Non-secure PA map, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the registers that control the stage of translation, TTBR0, TTBR1, TTBCR, and TTBCR2 are banked to provide independent Secure and Non-secure instances of the registers, and the Security state of the PE when it performs a memory access whether the Secure or Non-secure instances are used. This means that for stage 1 of the PL1&0 translation regime there are independent Secure and Non-secure translation tables, and translation table walks are made to the PA space corresponding to the Security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.
For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
  - The initial lookup performed must access the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 0, then the next level of lookup is from the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

For more information, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-5490.

- Otherwise, all memory accesses are to the Secure address space.

--- Note ---

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state, these are:
  - Non-secure EL2 stage 1 translation.
  - Non-secure PL1&0 stage 2 translation.

These translations can access only the Non-secure address space.

- A system implementation can alias parts of the Secure PA space to the Non-secure PA space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
G5.4 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections** Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of PA must also support Supersections to provide access to the entire PA space.

**Sections** Consist of 1MB blocks of memory.

**Large pages** Consist of 64KB blocks of memory.

**Small pages** Consist of 4KB blocks of memory.

Supersections, Sections, and Large pages map large regions of memory using only a single TLB entry.

--- Note ---

- Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.
- The EL2 translation regime cannot use the Short-descriptor translation table format.

---

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

**Level 1 table**

Holds *level 1 descriptors* that contain the base address and
- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

**Level 2 tables**

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as *translation tables*. A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A translation table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

*Figure G5-3 on page G5-5474* gives a general view of address translation when using the Short-descriptor translation table format.
Figure G5-3 General view of address translation using VMSAv8-32 Short-descriptor format translation tables

Additional requirements for Short-descriptor format translation tables on page G5-5477 describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in Figure G5-3.

VMSAv8-32 Short-descriptor translation table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5477, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-5478 describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

• Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G5-5478.
• Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G5-5479.

G5.4.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

• Short-descriptor translation table level 1 descriptor formats.
• Short-descriptor translation table level 2 descriptor formats on page G5-5476.

For more information about level 2 translation tables, see Additional requirements for Short-descriptor format translation tables on page G5-5477.

Note

Information returned by a translation table lookup on page G5-5469 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

Short-descriptor translation table level 1 descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G5-4 on page G5-5475 shows the possible level 1 descriptor formats.
Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

- **0b00, Invalid entry**
  The associated VA is unmapped, and any attempt to access it generates a Translation fault.
  Bits[31:2] of the descriptor are ignored, see `IGNORED on page Glossary-7463`. This means software can use these bits for its own purposes.

- **0b01, Translation table**
  The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MByte VA range.

- **0b10, Section or Supersection**
  The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.
  This encoding also defines the PXN field as 0.

- **0b11, Section or Supersection, if the implementation supports the PXN attribute**
  This encoding is identical to 0b10, except that it defines the PXN field as 1.

---

**Note**
A VMSAv8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting TTBCR.EAE to 0.

---

The address information in the level 1 descriptors is:

- **Translation table**
  Bits[31:10] of the descriptor are bits[31:10] of the address of a translation table.

- **Section**
  Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the translation table, Section, or Supersection. Otherwise, the address is the PA of the translation table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5477.

Short-descriptor translation table level 2 descriptor formats

Figure G5-5 shows the possible formats of a level 2 descriptor.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Invalid | IGNORED | 0 | 0 |
| Large page | Large page base address, PA[31:16] | TEX[2:0] | S | RES0 | C | B | 0 | 1 |

Figure G5-5 Short-descriptor level 2 descriptor formats

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

\[\text{0b00, Invalid entry}\]

The associated VA is unmapped, and attempting to access it generates a Translation fault.
Bits[31:2] of the descriptor are IGNORED, see IGNORED on page Glossary-7463. This means software can use these bits for its own purposes.

\[\text{0b01, Large page}\]

The descriptor gives the base address and properties of the Large page.

\[\text{0b1x, Small page}\]

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN field.

The address information in the level 2 descriptors is:

Large page  Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.
Small page  Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the translation table, Section, or Supersection. Otherwise, the address is the PA of the translation table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5477.
Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- Figure K7-14 on page K7-7297 for the level 1 translation table entry for a Supersection.
- Figure K7-16 on page K7-7299 for the level 2 translation table entry for a Large page.

Considering the case of using Large page descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these 16 index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

G5.4.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

TEX[2:0], C, B

Memory region attribute fields, see Memory region attributes on page G5-5513.

These fields are not present in a descriptor for a translation table.

XN bit

The Execute-never field, see Access permissions for instruction execution on page G5-5506.

This bit is not present in a descriptor for a translation table.

PXN bit

The Privileged execute-never field, see Access permissions for instruction execution on page G5-5506.

When this field is set to 1 in the descriptor for a translation table, it indicates that all memory pages described in the corresponding translation table are Privileged execute-never.

NS bit

Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-5478.

This bit is not present in level 2 descriptors. The value of the NS bit in a level 1 descriptor for a translation table applies to all entries in the corresponding level 2 translation table.

Domain

Domain field, see Domains, Short-descriptor format only on page G5-5510.

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.

This bit is not present in level 2 descriptors. The value of the Domain field in the level 1 descriptor for a translation table applies to all entries in the corresponding level 2 translation table.

An IMPLEMENTATION DEFINED bit

This bit is not present in level 2 descriptors.

AP[2], AP[1:0]

Access Permissions bits, see Memory access control on page G5-5502.

AP[0] can be configured as the Access flag, see The Access flag on page G5-5510.

These bits are not present in a descriptor for a translation table.

S bit

Shareable bit. Used in determining the Shareability of the addressed region, see Memory region attributes on page G5-5513.

Note

The naming of this bit as the Shareable bit is carried forward from early versions of the ARM architecture. This name is no longer an adequate description of the interpretation of the bit.
This bit is not present in a descriptor for a translation table.

**uG bit**
The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See Global and process-specific translation table entries on page G5-5525.

This bit is not present in a descriptor for a translation table.

**Bit[18], when bits[1:0] indicate a Section or Supersection descriptor**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### G5.4.3 Control of Secure or Non-secure memory access, VMSA v8-32 Short-descriptor format

*Access to the Secure or Non-secure PA map on page G5-5471* describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 descriptor for a translation table, the NS bit defines the PA map, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 descriptor for a translation table has no effect on the PA map in which that translation table is held. As stated in Secure and Non-secure address spaces on page G5-5471, the PA of that translation table is in:

- The Secure address map if the translation table walk is in Secure state.
- The Non-secure address map if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory maps is 1MB. However, in these memory maps, table entries can define physical memory regions with a granularity of 4KB.

### G5.4.4 Selecting between TTBR0 and TTBR1, VMSA v8-32 Short-descriptor translation table format

As described in *Determining the translation table base address in the VMSA v8-32 translation regimes on page G5-5470*, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of TTBCR.N indicates the number of most significant bits of the input VA that determine whether TTBR0 or TTBR1 holds the required translation table base address, as follows:

- If \( N = 0 \) then use TTBR0. Setting TTBCR.N to zero disables use of a second set of translation tables.
- If \( N > 0 \) then:
  - If bits[31:32-N] of the input VA are all zero, then use TTBR0.
  - Otherwise use TTBR1.

Table G5-1 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1 translation table addressed by TTBR0.

#### Table G5-1 Effect of TTBCR.N on address translation, Short-descriptor format

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Size</td>
</tr>
<tr>
<td>0b000</td>
<td>TTBR1 not used</td>
<td>16KB</td>
</tr>
<tr>
<td>0b001</td>
<td>0x80000000</td>
<td>8KB</td>
</tr>
<tr>
<td>0b010</td>
<td>0x40000000</td>
<td>4KB</td>
</tr>
<tr>
<td>0b011</td>
<td>0x20000000</td>
<td>2KB</td>
</tr>
<tr>
<td>0b100</td>
<td>0x10000000</td>
<td>1KB</td>
</tr>
</tbody>
</table>
Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G5-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Figure G5-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format

In the selected TTBR, bits RGN, S, and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

G5.4.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.

Reading a level 1 translation table on page G5-5480 describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the level 1 descriptor.

Reading a level 1 translation table on page G5-5480 shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages on page G5-5480 then shows the complete translation flow for each valid memory access.

Table G5-1 Effect of TTBCR.N on address translation, Short-descriptor format (continued)

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table</th>
</tr>
</thead>
<tbody>

<td>0x04000000</td>
<td>256 bytes</td>
</tr>
<tr>
<td></td>
<td>VA[25:20]</td>
<td></td>
</tr>
<tr>
<td>0b111</td>
<td>0x02000000</td>
<td>128 bytes</td>
</tr>
<tr>
<td></td>
<td>VA[24:20]</td>
<td></td>
</tr>
</tbody>
</table>

Boundary, when TTBCR.N==0b111
Reading a level 1 translation table

When performing a fetch based on TTBR0:
• The address bits taken from TTBR0 vary between bits[31:14] and bits[31:7].
• The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the TTBR0 and VA fields depend on the value of TTBCR.N, as Figure G5-7 shows.

When performing a fetch based on TTBR1, Bits TTBR1[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in Figure G5-7, with N==0.

Note
See The address and Properties fields shown in the translation flows on page K7-7300 for more information about the Properties label used in this and other figures.

Figure G5-7 Accessing level 1 translation table based on TTBR0, Short-descriptor format

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:
• A level 1 descriptor for a Section or Supersection.
• A descriptor for a translation table, that points to a level 2 translation table. In this case:
  — A second fetch is performed to retrieve a level 2 descriptor.
  — The descriptor also contains some attributes for the access, see Figure G5-4 on page G5-5475.
• A faulting entry.

The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the initial lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:
• The table descriptor read in the previous lookup.
• The input address.

Address translation examples using the VMSAv8-32 Short descriptor translation table format on page K7-7296 shows the full translation flow for each of the memory section and page options. As described in VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5474, these options are:

Supersection  A 16MB memory region, see Translation flow for a Supersection on page K7-7296.
Section        A 1 MB memory region, see Translation flow for a Section on page K7-7297.
Large page  A 64KB memory region, described by the combination of:
   • A level 1 translation table entry that indicates the address of a level 2 translation table.
   • A level 2 descriptor that indicates a Large page.

See Translation flow for a Large page on page K7-7298.

Small page  A 4KB memory region, described by the combination of:
   • A level 1 translation table entry that indicates the address of a level 2 translation table.
   • A level 2 descriptor that indicates a Small page.

See Translation flow for a Small page on page K7-7300.
The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory Pages, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to blocks of memory, where a block can be 2MB or 1GB.

--- Note ---

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G5-2 on page G5-5461 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure EL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address, then this address is zero-extended to 40 bits.

--- Note ---

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

Overview of VMSAv8-32 address translation using Long-descriptor translation tables summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

The following sections then describe the format of the descriptors in the Long-descriptor format translation tables:

- **VMSAv8-32 Long-descriptor translation table format descriptors** on page G5-5483.
- **Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors** on page G5-5486.
- **Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format** on page G5-5490.

The following sections then describe this translation table format:

- **Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format** on page G5-5491.
- **VMSAv8-32 Long-descriptor translation table format address lookup levels** on page G5-5493.
- **Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-5497.**
- **The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format on page G5-5500.**

G5.5.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G5-8 on page G5-5483 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.
Figure G5-8 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G5-9 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

Figure G5-9 General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format

Use of concatenated translation tables for the initial stage 2 lookup on page G5-5494 describes how using concatenated level 2 tables means lookup can start at level 2, as referred to in Figure G5-9.

G5.5.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G5-5493, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at level 1 or level 2 of the address lookup.

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:

- VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats on page G5-5484.
- VMSAv8-32 Long-descriptor translation table level 3 descriptor formats on page G5-5485.
Information returned by a translation table lookup on page G5-5469 describes the classification of the non-address fields in the descriptors between address map control, access controls, and region attributes.

VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

Figure G5-10 shows the Long-descriptor level 1 and level 2 descriptor formats:

**Descriptor encodings, Long-descriptor level 1 and level 2 formats**

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block
  - The descriptor gives the base address of a block of memory, and the attributes for that memory region.

- 1, Table
  - The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

**Block descriptor**

Gives the base address and attributes of a block of memory:

- For a level 1 Block descriptor, bits[39:30] are bits[39:30] of the output address that specifies a 1GB block of memory.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G5-5548.
Bits[63:52, 11:2] provide attributes for the target memory block, see *Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5486*. The position and contents of these bits is identical in the level 2 block descriptor and in the level 3 page descriptor.

**Table descriptor**

Bits[39:m] are bits[39:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:
- For a level 1 Table descriptor, this is the address of a level 2 table.
- For a level 2 Table descriptor, this is the address of a level 3 table.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see *Address size fault on page G5-5548*.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see *Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5486*.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

### VMSAv8-32 Long-descriptor translation table level 3 descriptor formats

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

*Figure G5-11* shows the Long-descriptor level 3 descriptor formats.

---

**Valid**

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- **0, Reserved, invalid**
  - Behaves identically to encodings with bit[0] set to 0.
  - This encoding must not be used in level 3 translation tables.

- **1, Page**
  - Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

If bits[47:40] of the descriptor are not zero, then a translation that uses the descriptor will generate an Address size fault, see *Address size fault on page G5-5548*.

Bits[63:52, 11:2] provide attributes for the target memory page, see *Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5486*. The position and contents of these bits are identical in the level 1 block descriptor and in the level 2 block descriptor.
